Grapes for Verandah.—B. T.—Your verandah 30 feet long and 6 feet wide would afford room for four vines; and the best sorts for the purpose are *Esperione*, Cambridge Botanic Garden, *Grove-End Sweetwater*, and *Chasselas Violet*. The article on pruning the vine to which you refer will be found at page 14 of the present volume (Jan. 12, 1867).

Sonnet Amateur.—One vine will be quite enough for your little house, but you may plant the three, and restrict them. The border you propose will answer well, if it is really drained. You speak of putting clinkers on the surface. You are, we suppose, aware that clinkers laid on the soil will not promote the escape of water; probably you mean that the clinkers form the foundation. If you want to grow choice greenhouse plants in the house, you

advise you not to plant vines at all. The double *Sanvitalia procumbens* is a pretty annual.

Hedychium Gardnerianum.—Ensigne.—This fine plant grows to a height of six to ten feet, and flowers gloriously if well managed. The principal requisites of success in the cultivation of the plant are five in number, namely, a light rich sandy soil; a sufficient temperature when growing, say 70° to 90°; abundance of water while growing; a thorough rest, with small allowance of water, in a temperature of 45° to 60°; full exposure to light at all seasons. Propagation is effected by division. The best compost for them is one consisting of equal parts mellow loam, leaf-mould, thoroughly rotten hotbed manure, and sharp sand. They are sometimes grown in peat, but a mixture without peat is preferable.

** The Editor can recommend a person possessed of spirit, ability, and probity as Head Gardener in a garden where pines, grapes, and orchids are grown. His testimonials are all that can be desired, and he is prepared to take a fresh place at once. Letters addressed to G. G., care of the Editor, will have prompt attention.

WHAT BECOMES OF STRAY DOGS?

While searching for artificial manures, I was directed to a man who was reported to prepare a cheap and powerful manure from the stewed carcasses of stray dogs. I was a little amused, and obtained the services of a friend who is one of the principals in a great nursery firm, somewhere to the north of the metropolis, and less than a thousand miles distant. At the time of my expedition, harvest was in progress, and the weather was rainy. As we drove along a narrow lane in a very romantic spot, mutually regretting that a piece of oats in the harvesting of which my friend was particularly interested seemed likely to be much injured by the weather, I noticed in a field near the road a low shed-like building, with a chimney from which a thin column of smoke rose slowly. "What's here?" I asked, "a pottery or a steaming apparatus for cattle food, or are they kiln-drying the wet corn?" My friend smiled, and replied, "That is the place you are bound for—that is the manure factory. We will not go in yet, or at all if we can help it, for it's not a nice place, but drive down to the proprietor's house, and look for him first." I shall not narrate all that happened, or give any opinion (at least just now) upon the dead-dog manure. But a few particulars of the industry may be interesting both to lovers and haters of the canine race. Well, to begin the story, the London police are now authorized to catch and kill stray dogs. They follow their instructions with vigilance, and mayhap with gusto. They catch and kill, and the dead dogs are transferred by night in carts or wagons to this spot, and here they are boiled down just as they are, skins, hair, and all. They are tossed into the cart in a solid mass, and as soon as they arrive they are taken out of the cart by means of pitchforks, and thrown at once into the coppers, or piled up in heaps ready for the next hoil. The men employed make it a rule never to touch them with their hands if they can help it, and the prejudice against handling them is the reason for boiling them whole without peeling, else no doubt the skins would pay better as leather than as glue, or whatever else is got out of them. Some of the dogs, perhaps, are mad when the police kill them; all of them, perhaps, have been killed by poison; some, for certain, are in a dreadful state of disease when their lives are extinguished. These are doubtless good reasons for sacrificing their skins for manure and glue rather than keeping them for leather. It occasionally happens that, as the cart comes along at night, a whine or faint yelp is heard from the midst of the canine corpses. The carman is not alarmed; he has heard such a noise before from the unsightly heap, and he just takes hold of a small pole-axe which he carries with him for the purpose, and proceeds to discover which of the corpses has come to life again, that he may knock it on the head. The fact is, a dog now and then escapes complete killing, the poison administered acting only as a powerful narcotic, from which, after long sembling death, and being kicked, forked, and jammed in the mass, the poor wretch begins to revive, and perhaps struggles to the top, and gets a gulp of reviving fresh air ere emitting the expression that secures his second execution. More than once a handsome dog, not very much hurt either by pitchfork or poison, has sat up in the cart and begged to be spared his ignominious doom, and has gained a tender hearing, and now lives to tell the tale for the benefit of all dogs given to straying. As a rule, however, it is a merciful proceeding to finish the revivalists, for if spared it would only be to suffer and drag on for a brief space of time a miserable existence. The consignment of dead dogs to this particular factory has for a long time past averaged *two tons weekly*. TOM TIDDLER.

HEIGHT OF AUSTRALIAN GUM TREES.

The marvellous height of some of the Australian, and especially Victorian, trees has become the subject of closer investigation, since of late, particularly through the miners' tracks, easier access has been gained to the back gullies of our mountain system. Some astounding data, supported by actual measurements, are now on record. The highest tree previously known was a *Kauri-Eucalyptus* (*Eucalyptus eolossca*), measured by Mr. Pemberton Walcott, in one of the delightful glens of the Warren River of Western Australia, where it rises to approximately 400 feet high. In the hollow trunk at this kauri, three riders, with an additional pack-horse, could enter and turn in it without dismounting. On the desire of the writer of these pages, Mr. D. Boyle measured a fallen tree of *Eucalyptus amygdalina* in the deep recesses of Dandenong, and obtained for it the length of 420 feet, with proportions of width indicated in a design of monumental structure placed in the exhibition; while Mr. G. Klein took the measurement of a *Eucalyptus* on the Black Spur, ten miles distant from Healesville, 480 feet high. Mr. E. B. Heyne obtained at Dandenong as measurements of heights of a tree of *Eucalyptus amygdalina*: Length of stem from the base to the first branch, 295 feet; diameter of the stem at the first branch, 4 feet; length of stem from first branch to where its top portion was broken off, 70 feet; diameter of the stem where broken off, 3 feet; total length of stem up to place of fracture, 365 feet; girth of stem 3 feet from the surface, 41 feet. A still thicker tree measured 3 feet from the base, 53 feet in circumference. Mr. George W. Robinson ascertained, in the back ranges of Berwick, the circumference of a tree of *Eucalyptus amygdalina* to be 81 feet, at a distance of four feet from the ground, and supposes this eucalypt towards the sources of the Yarra and Latrobe Rivers to attain a height of half a thousand feet. The same gentleman found *Pagus Cunninghami* to gain a height of 200 feet, and a circumference of 23 feet. Ner is it at all likely that in these isolated inquiries chance has led to the really highest trees, which the most secluded and least accessible spots may still conceal.—PROFESSOR MUELLER, of Victoria, in "Seaman's Journal of Botany," July, 1867.

The Gardener's Magazine.

SATURDAY, NOVEMBER 9, 1867.

THE CAUSES OF SUCCESS IN FRUIT CULTURE are not wholly under the direction of human intelligence. The various stocks on which the several varieties of fruits are grafted, the various modes in which trees are planted, pruned, trained, and otherwise tended, exercise their respective influences on the final result. But the most important matter of all is THE INFLUENCE OF CLIMATE. The best practice possible will not suffice to produce luscious peaches in the open air in the bleak climate of the North Cape, nor sprightly-flavoured apples in the hot and arid atmosphere of Idumea. It must be granted that to grow fruit well there must be something known of the best modes of training, pruning, planting, and so forth; but the foundation of success lies in adapting, in the first instance, the kinds of fruits to the climate in which they are to be cultivated. If we are wrong in our modes of training, we can be taught better. We may even go so far as to say that if the soil is unsuitable we can alter it, for, in the very worst of cases, we can do something to improve its texture, condition, and constituents. But what are we to do if the climate is against us? We are then driven to the employment of glass, of walls, of apparatus for the production and diffusion of artificial heat. Simple fruit culture in the open air is an affair of climate chiefly, every other condition of success is secondary to that; give us a suitable climate, and we will somehow or other accomplish all the rest. We fear this very simple and very self-evident consideration of the subject of fruit culture does not obtain sufficient attention. There is a brisk discussion in progress as to the relative merits of English and French modes of fruit cultivation, and the parties who have taken the most prominent part in it appear to undervalue the fact that there are some differences discoverable in the climates of the two countries. We may not be far wrong in alleging that it has been boldly asserted that between London and Paris there is no appreciable difference of climate; but the facts of nature are against the allegation, and we invite our readers to consider this subject for a few moments, as the conclusions arrived at may bear very directly on English practices, and the influence upon them of the examples and practices of our neighbours.

Between London and Paris there are 2° 40' difference of latitude, that of London being 51° 30', that of Paris 48° 50'. According to Humboldt, this should make a difference of about 4° in the mean annual temperature of the two cities. Now, the actual difference in the mean annual temperature is only 0° 53, the mean of London being 50° 8, that of Paris 51° 1. The energies of vegetation are less influenced by mean annual temperatures, however, than by winter minima and summer maxima; and if we compare the two localities selected for the present argument in respect of the two extremes, we shall find that the Parisians enjoy some special advantages over us. The mean temperature of the month of October in Paris is 51° 3, which is very nearly the mean of the year, but in the same month the mean of London is 52° 3. Again, in April the mean of Paris is 48° 2, that of London 49° 8. The mean temperature of the winter in Paris is 38° 7, that of London 37°. Again, the mean of the hottest month in Paris is 69° 8, the mean of the hottest month in London is 64°. Reference to any good map of the distribution of temperature over the surface of the earth (such as one of Keith Johnston's, or Mr. Petermann's map in Milner's "Gallery of Nature," or those in Mr. Alexander Buchan's admirable Handy Book of Meteorology) will show that the isothermal line of 50°, which dips so low on the American continent as the 40th parallel, rises to the 54th parallel in the course of the Gulf Stream to the north-west of Ireland, and then passes down in a slanting course through Dublin, London, Brussels, and Vienna, the Gulf Stream affording to us, and to the west of Europe generally, a higher mean than is due to latitude alone. But even in respect of this mean, it will be seen that Paris has the advantage of us. The capital of France enjoys a higher mean temperature than Vienna, though it is half a degree farther north than Vienna; and London enjoys the same mean temperature as Brussels, though it is 40 minutes, or two-thirds of a degree, farther north than Brussels.

No. 132, NEW SERIES.—VOL. X.

Restricting the comparison to the respective climates of London and Paris, it will be observed that in London the extreme cold of winter is severer than in Paris to the extent of 1° 7 Fahr. This difference is literally of no consequence at all; a few degrees more cold in winter cannot affect our fruit prospects seriously; possibly we have the advantage in that matter. In April, the London temperature is 1° 6 Fahr. higher than that of Paris, and here is our first disadvantage. Our climate is much more variable everywhere than the climate of France; the outbursts of hot weather we experience almost every year in March and April cause a premature activity of the sap in fruit-trees, and they begin to grow and flower ere the season is sufficiently advanced to sustain their activities. It is quite true that in French orchards the crop is occasionally destroyed by untimely frosts; but we are much more exposed to that danger, and the reason of it may be seen in the fact that the Paris mean in April is 48° 2, that of London 49° 8.

But when the summer has commenced, the temperature of Paris rises higher than that of London, and the maxima of the cities differ to the great extent of 5° 8 Fahr. Now, a difference amounting to within a fraction of 6 degrees of Fahrenheit is something enormous in the consideration of the subject now before us. Students of climatology know that a difference of only 2° either way in the heat of the summer of Great Britain will make a difference to the extent of a bountiful harvest and prosperity, or a meagre harvest and starvation. It cannot be wondered at that the cultivators of fruits in the neighbourhood of Paris should outstrip the growers of fruits in the neighbourhood of London, especially in the production of peaches, cherries, and pears; for they have the advantage to the extent of six degrees, and no skill of man can find a compensatory equivalent for so much solar heat and light by which to place the London cultivator on terms of equality with the Parisian. Observe, again, that when the summer is past London is warmer than Paris, for in October the London mean is 52° 3, and that of Paris is 51° 3, a difference of exactly one degree. Possibly some of our fruit-growing friends may consider that London is the gainer thereby; but our own opinion is that the Parisian pomologist is directly advantaged, for, after having had a brisk growing and fruiting season, the cooler autumn disposes his trees more immediately to rest; he has the advantage, in fact, of one degree for the prevention of late and useless growths, to add to his advantage of six degrees for better growing and ripening, and the advantage in April of one and a half degrees (1° 6 Fahr.) for retarding the bloom and leafage of his trees until the danger of frost is past. Here are three signal advantages in respect of temperature enjoyed by the cultivators of Paris over the cultivators of London; and what is true of the two cities is true of the two countries; and if we were to make a more extensive comparison, we should find more striking differences. What does M. Baltet, of Troyes, say upon the subject in that able and interesting paper of his which we published last week? He says, "We are sheltered from the rigorous cold of the north, from the burning heat and dry winds of the south, from the salt breezes which blow from the sea-shore, and from the sudden changes of temperature which generally occur in the neighbourhood of mountain ranges, checking the normal vegetation, the fecundation of the flower, and the growth of the fruit. Then add to this happy climate the geographical position so favourable to the transportation of our wares; the proximity to the capital, the means of transport by railway, by water, or by our admirable roads, the easy access to Paris and London, as well as to Belgium and Germany" (vide G. M., Nov. 2, 1867, p. 468).

When, therefore, it is asserted that French methods are applicable without reserve to English gardens, and that whatever French cultivators can do can be done as well by English cultivators, we reply that such assertions are made in ignorance or in defiance of the facts of climatology, and the wise man will not invest his money or his land or his time (and the term "money" comprehends all these with talent added) in the introduction of French systems, until he has fully considered how far the subject of climate may be associated with the chances of success. Let it not be thought that the GARDENER'S MAGAZINE is an enemy to improvement. All we wish to do in respect of these discussions on fruit cultivation, is to direct attention to the facts on which opinions should be formed and

practice founded. English growers have been much beguiled by starving stocks and excessive pinching, and we have no desire to see developed any new phases of delusion in the English fruit garden.

MR. SALTER'S EXHIBITION OF CHRYSANTHEMUMS at the "Versailles Nursery," William Street, Hammersmith, is now in its full splendour. As usual, Mr. Salter has some fine seedlings both of the large-flowering and pom-pom kinds, and the exhibition is enriched with interesting examples of ornamental foliage and other subjects of like suitability.

MR. FORSYTH'S EXHIBITION OF CHRYSANTHEMUMS at the "Brunswick Nursery," opposite West Hackney Church, Stoke Newington, was opened on Wednesday last, and the flowers are now beautiful. There are several good novelties here, and the general display will afford much gratification to visitors.

THE EAST TOWER HAMLETS SOCIETY'S EXHIBITION OF CHRYSANTHEMUMS will be held at the Edinboro' Castle Tavern, Rhodeswell Road, Stepney, on Monday and Tuesday next, the 11th and 12th of November.

THE STOKE NEWINGTON CHRYSANTHEMUM SOCIETY'S EXHIBITION will take place in the School-room connected with Abney Chapel, Church Street, Stoke Newington, on Thursday and Friday next, the 14th and 15th of November.

THE NORTH-WESTERN CHRYSANTHEMUM SOCIETY'S EXHIBITION will be held in the large room of the Railway Institute, Chalk Farm, on Wednesday, Thursday, and Friday next, the 13th, 14th, and 15th of November.

THE BRISTOL CHRYSANTHEMUM SOCIETY'S EXHIBITION will be held on Thursday next, the 14th of November.

THE SOUTH ESSEX CHRYSANTHEMUM SOCIETY'S EXHIBITION will be held in the Artillery Hall, Stratford, on Tuesday and Wednesday, the 19th and 20th of November.

THE BRIXTON HILL CHRYSANTHEMUM SOCIETY will hold its Annual Exhibition in Christ Church School-rooms, Roupell Park, Brixton Hill, on Tuesday and Wednesday, the 19th and 20th of November.

THE EAST LONDON AMATEUR SOCIETY'S EXHIBITION OF CHRYSANTHEMUMS will be held in the Vestry Hall, Bow, on Thursday and Friday, the 21st and 22nd of November.

A SHOWER OF METEORS OR BOLIDES, on a grander scale than that of last year, is anticipated by astronomers on the night of Thursday or morning of Friday next. It is expected to attain its maximum splendour about four a.m. on Friday.

RIPE STRAWBERRIES are less abundant now than at this time last year; but we have seen a few of the Alpine varieties fully grown and nearly ripe during the past week, and we have now before us a very handsome berry, three-parts ripe, which was taken from a garden at Tulse Hill and brought to us by Mr. Chitty. The sharp frost of Sunday last no doubt made an end of the strawberry season everywhere.

RICINUS COMMUNIS at Stoke Newington survived the frost of October 8th, and remained fresh four weeks after dahlias, vegetable marrows, kidney beans, and other tender subjects were destroyed. But the sharp frost of Saturday and Sunday last destroyed the Ricinus, and we may now properly believe that the summer is at an end. Chrysanthemums are not in the least injured by the frost of Sunday last, which amounted to 7 degrees.

OCTOBER 10 was observed throughout the Canadian dominion as a day of thanksgiving for an abundant harvest. The crops in Canada this year are reported to have yielded as bountifully as those in the United States.

THE CHINESE TALLOW TREE.—The tallow tree of China has been transplanted in the Punjab with great success. Dr. Jameson has prepared hundred-weights of grease from it, and has forwarded on trial a portion of it to the Punjab Railway, to have its qualities tested as a lubricant. The grease thus obtained, it is said, forms an excellent tallow, burning with a clear, brilliant, and white light, emitting no unpleasant odour or smoke.

OVER-CULTIVATION OF THE POTATO.—In an article on the high prices of provisions in the *City Press* of last week occur the following remarks, which, whether we agree with them or not, certainly deserve attention, for it is quite a question if the potato is entitled to the extent of space allotted to it in gardens, since it has become to all appearance a permanent prey to disease: "The agriculturists must bear some of the blame of high prices, though they are not much benefited by them. High prices are simply tantalizing to a man who has no crop to sell, and the extensive failures of cereals in the present year have made this a dark time for farmers. But there are two points in agricultural practice in respect of which the agrarian classes are to blame, and the first is the too restricted cultivation of meat, and the over-extended cultivation of potatoes. There has never before probably been so large a breadth of land planted with potatoes as in 1867, and never before probably been so general a devastation of the crop by disease. Every farmer in the land should have known that this would be a cold season, and that a cold season is of necessity fatal to the potato, which lives on sunshine, even more than wheat does. The potato crop is almost wholly lost, and the entire community must pay for the loss in the end, though it falls first on the farmer. The darkness of the agricultural mind contributes its portion of gloom in this way to every man's household."

EARLY WINTER.—A letter from Briançon (Hautes-Alpes) states that snow has fallen heavily in that neighbourhood, and in a few hours lay upwards of a foot deep. The passengers by the Grenoble diligence had to get out and walk three miles, nearly up to the knees in snow, the storm during the night being so violent as to prevent the road being cleared. The agriculturists will suffer considerably, as much of the after-growth on the artificial meadows is still uncut, and the potato-digging is not yet terminated.

SILKWORMS IN CALIFORNIA.—Mr. Prevost, a famous silkworm breeder in California, writing to the American Board of Agriculture, says: "Just a month ago I was in Sacramento, and think how pleased I was to find that over 3,000,000 of mulberry trees were growing there finely in different places. And I found also that Mrs. Haynie had a fine crop of cocoons—the finest I have ever yet seen. The question is now settled that the mulberry tree and the worms succeed finely all over our State; but, by what I see, Sacramento will be the first silk district of California. I think that for the next season they will have there food enough for 10,000,000 silkworms."

AGRICULTURAL RETURNS FOR GREAT BRITAIN IN 1867.—We are favoured with the following official return from the Statistical Department of the

Board of Trade: The aggregate of these returns has just been made up, and under corn crops of all kinds there were in England and Wales 7,941,578 acres, against 7,921,244 acres returned in 1866; and in Scotland 1,367,012 acres, against 1,366,540 acres in 1866. The land under wheat is returned for England and Wales at 3,255,917 acres, against 3,275,293 acres in 1866; and for Scotland at 115,118 acres, against 110,101 acres in 1866. The number of cattle is returned for England and Wales as 4,017,790, against 3,848,435 in 1866; and for Scotland as 979,170, against 937,401 in 1866. Sheep are returned for England and Wales to the number of 22,097,286, against 16,793,204 in 1866; and for Scotland to the number of 6,893,603, against 5,255,077 in 1866. The large increase in the number of sheep returned in 1867, as compared with the previous year, is to be accounted for by the fact that the returns in 1866 were made for the purpose of the Cattle Plague Inquiry at a date preceding the lambing season in some parts of Great Britain.

MR. JABEZ J. CHATER'S GONVILLE NURSERIES, CAMBRIDGE.

Mr. Chater's nurseries occupy a delightfully-rural position, within view of the big elm-trees that hug the colleges in the rear of Trumpington Street, Cambridge. The day of my visit, in the middle of September last, was bright and bracing, and I spent a couple of hours very pleasantly in rambling about the place, with Mr. Willers, the able foreman, who, in Mr. Chater's absence, played cicerone admirably, and took care I should miss nothing that was at all likely to interest me. The nurseries cover about eight acres of ground, and are as interesting as some that cover eighty. It does not need to be said that mere superficial area is no measure of value or excellence in a matter of this sort. There is an ample extent of glass, and good collections of stove and greenhouse plants of all kinds, and a remarkable collection of zonal and variegated-leaved pelargoniums, mostly of Mr. Chater's own raising. Hardy trees and hardy herbaceous plants are largely grown, and collectors of such things are sure to find here a few rarities amongst species and varieties that are desiderata in all good gardens. All about the place were beds of pelargoniums, many of them evidently in advance of the average character of the classes to which they belong, and all in a superior style of keeping, and creditable alike to the cultivator and to the pure air of the locality. Whether by instinct or whatever other impulse, I made for the geraniums, and soon found enough to occupy a few days of leisurely criticism, if the days could be spared; but, as hours were scarcely at my service, I at once made note of a few most select kinds, that our selectest collectors may book as necessities of life; for I can assure you the best of Chater's are among the very best that exist. Imprimis, for a collection to show for large, round, thick, richly-coloured, genuine florists' flowers, take *Mary Eveline*, a zonal with huge flowers of a clear pleasing peach colour; *Beauty*, a zonal with large round blush flowers; *Acme*, rosy scarlet, superb; *Crimson Queen*, grand crimson scarlet, quite a desirable colour, and the quality first-rate; *Seraphine*, clear salmon-flesh, fine form and substance; *Estival*, one of the most magnificent rose-coloured varieties in existence; *Fiery Star*, a brilliant scarlet; and *Eunice*, a charming rosy scarlet. There are hundreds of good varieties here, and, indeed, there are few grown except their own, and they constitute a race peculiar to the place, just as the tulips and gladioli at Stapleford, hard by, do in the garden of Mr. Heady. Let us now try the variegated section. *Yellow Sovereign* is the name given to the one I praised so highly in the *Geranium Papers* as Chater's "mysterious 240." Here I saw it blazing like a sheet of Cloth-of-Gold, beating Goldfinch and Canary, and all the newer lot of yellow "unicolors" of Chater's classification, and "golden-leaved" of my classification. For a glorious golden pavement, go in boldly for "Yellow Sovereign." Once more I was very much pleased with *International*, which I find characterized in my note book as offering a "grand contrast between leaf and flower." The leaf is bright sulphur-green, the flowers are bright carmine. This would make a capital companion bed in a geometric system to F. and A. Smith's Aureum, which has been already characterized in these pages as one of the best yellow-leaved geraniums known.

Next we turn to the variety described in No. XLII. of *Geranium Papers* (Aug. 10, 1867), the nearest to which in the old varieties is Daybreak. This of Chater's is called *Silver Ring*; it is perfect in style of growth, purity of colouring, and hardihood of constitution. I would as soon order a thousand of it direct, and plant it for the front of a fifteen hundred feet of ribbon, at 18 inches apart, as I would order so many chaldrons of coke for the furnace fires, being as well satisfied as to the result in one case as the other, and having no idea of risk about it. Again, we look for another of my favourites, and find it under the name of *Saturn's Ring*. This is a richly-coloured bronze zonal, the zone being of a light rust-red colour, laid sharply on a strong yellow ground; it is a capital bedder, and very telling when viewed in the mass from any distance. *Sulphur Queen* is also good in this way; it is a golden-leaved variety, very clear and distinct in colour, with excellent habit of growth. Plenty more such; but none of us expect to live for ever in these scenes, and therefore we will hasten to another section of this great pelargonium family. Some remarkable nosegay varieties here, and one amongst them that must attain to lasting fame. What do you say to a white-flowering nosegay in the style of *Stella*? Well, here is such an one, and its name is *Sprite*—a bad name, I will say, for sprites are generally blue, black, and red, and very evanescent in their appearances, and always bent on evil missions. The name to sell it by is *White Stella*. By St. Nomenclator, I'll find names for flowers at a crown each, money first: I've named thousands for nothing hitherto. But to return to the *Sprite*, I can assure you it is a capital thing, grows well, blooms abundantly, and stands any weather. Another good one is *Stella's Spouse*, the habit neat and pretty, the flowers pleasing light pink. *Thor* is a dwarf nosegay with purplish scarlet flowers. *Arthur B. Chater*, with versicolor foliage (golden zonal of our system) and puce crimson flowers; fine. *Fiery Queen*, with light zone and lively orange scarlet flowers; good for all who want yellowish geranium flowers, and for such as are aiming to breed pure yellows; may they live to see them, and no'er grow old or cold! Another in the same line is *Orange Prince*, a companion to *Le Grand*, and by its strong tone of orange well calculated to bring out the purplish tone of *Le Grand*. Clear out of the track as respects colour, but entitled to lead and govern, is *Robert Fish*, a most worth souvenir of one of the worthiest of men. The colour of the flowers is crimson-scarlet, or very nearly what is called pure crimson in the silk and sarenet trade; the trusses put together with wondrous solidity and taste. I am sorry I missed two more in the same class—*Satisfaction* and *Alex. McKay*. Next time I go to Cambridge, I shall inquire about them. If I were buying now, I should order them at a risk; but I don't advise that course, for there are plenty of good things to be got without risk. Have patience

with me while I pick out three more, and then I will leave you to study Chater's catalogue, and select further for yourself. *Christine Surpass* is a bonny thing, with benet-like (old fashioned bonnet-like) flowers of great substance, and a delicate clear Beauté du Suresno colour. *Fearnought*, a scarlet, with clear large white eye; the form of the flower most beautiful. If you can afford to order only one of this glorious batch, have *Fearnought*, if only for the joy of discovering that, in the midst of thousands of scarlet geraniums, a new and distinct character may yet be found. *Enchantress* is a painted flower, the centre rosy salmon softly shading to white margin, the petals stout and broad, and the flower finished with exactitude. Now I've done with these things, and sorry am I that I dare not say more.

Mr. Willers looked so proud and defiant when I asked after herbaceous plants, that I did not need his reply, that they had a few. A few! I was agreeably surprised to find they had many, and some very choice subjects too. Of course such things as Rudbeckias, Inulas, Asters, Phloxes, Sedum spectabile, and (Gnotheras, were at their best at the time of my visit, but the stocks of all good things are good; there are primulas, violas, swallow-worts, saxifrages, coronillas, spireas, &c., &c., &c., &c., too many to count; and the pick and prime of the best herbaceous lists are grown in as great quantities as the laws of propagating them permit, to meet the great and increasing demand for such things. Lots of things live out here the winter through that we cannot make sure of near London. The two Plumbagos, *Larpena* and *Capensis*, live out; all the Rudbeckias ditto; and so on with many other good things. I found here the scarce *Viola papilionacea*, which has a bulbous or rather tubercous root, and produces flowers that remind one of butterflies and bean-blossoms. A great stock too of the double crimson and white rockets. How delightful it must be to live within hail of a place where the double rockets have justice done them, and to have the shelter also of the College elms, to know the classic Cam flows quietly by, and to hear the soft swell of the organ in King's College Chapel when the thrushes pause in their songs during service hours! Happy Mr. Chater, yours is the very spot Prince Rasselas of Abyssinia—a better prince than Theodore of these degenerate days—searched all his life for, and died without finding it!

A turn amongst what Mr. Willers calls the "pictorial trees" ended my hurried survey. Well, all trees are pictorial, more or less. A gigantic beech, standing all alone in a great space of greensward, is one of the most picturesque objects in nature. A group of cloud-aspiring elms, with a bit of homely thatch and a wreath of azure-blue smoke curling up amongst their branches, go some way towards the formation of a picture. But horticultural and arboricultural people who talk about pictorial trees have in mind such things as *Liquidambar styraciflua*, with its fingered leaves, dying off now a rich purple-red with splashes and sparks of flame-colour and amber, or the drooping variety of *Sophora Japonica*, the dark leaves of which clothe pendent branches that fall like ringlets, or the "Eagle's claw" maple, the leaves of which are lobed and cut in close resemblance to the foot of some great bird; or the elegant, fairy-like weeping birch, which weeps indeed, with the pensive, pensile, and penitential attitude, as if doing penance for all the trees in the wood. There is a large stock of elegant trees in almost endless variety here—the ghostly *Negundo*, the fern-like *Salisburia*, several *Poplars*, with leaves snow-white on the under-side; the variegated-leaved *Walnut*; all the slender-stemmed and drooping *Willows*, the *Scampston Elm*, the *Weeping Lime*, the *Calyanthus floridus*, from which you may snap a twig now and then as you walk about the garden, in order to induce a reverie of cinnamon groves, and that blest isle "where spices breathe and fragrant roses smile." On the way out I noted two good bedding plants—*LOBELIA erinus sueciosa picturata* (first and last names enough for ordinary purposes) is a capital dwarf habited variety, with dark-blue flowers. *Tropaeolum Lobbianum Premier* is eminently effective; the leaves small and of a dark colour, the flowers deep crim-on-scarlet; fine. Lovers of fuchsias would do well to look after one here called *Magniflora*; it is a huge double flower, colours purple and red; extremely rich and bouncing. S. H.

VARIEGATED LEAVED TREES AND SHRUBS FOR ORNAMENTAL PLANTING.

A visit recently to a nursery celebrated for an extensive collection of hardy pictorial trees, both evergreen and deciduous, has suggested to me several ideas in relation to ornamental planting which possibly may assist or interest such of our readers as are at this, the most seasonable portion of the year, about to add to those they may already possess; and as my mission was to purchase some of the most beautiful of them, I had therefore, in the course of my selection, ample opportunity of noticing their peculiar attractions. When speaking of ornamental planting, I do not think that in this department of gardening we have made progress corresponding to what we have done in other branches of our profession. In fact, there is a wide field open for improvement, not only in our choice, but in the distribution of our trees and shrubs. When planting we sometimes show an absence of taste; for too often are several plants of the same variety crowded together, for no other purpose but that of shutting out some objectionable view, or that of defining a boundary; and this is frequently done without any consideration as to the size, both in bulk and height, they will from their permanent position gain in the future. Certainly there are exceptions to this rule, but they belong more especially to public than to private gardens. If we allude to the conifers and their allies, we shall find that in many private gardens there are some glorious examples of good taste in their distribution for effect, and also superior culture in regard to their training and general uniformity of growth. The care thus given may partly be attributed to the grace and dignity of contour which belong to this class of plants, and which render them specially adapted for being cultivated as single specimens planted on lawns, or in any other situations where there are no other objects likely to detract from their beauty. Passing from this, in connexion with our subject, we may observe that our present system of flower-garden bedding has never been equalled in the annals of gardening. We may then ask, what is it that has tended so considerably of late years to enhance its beauty? Why, it is the addition to the list of bedders of the many variegated or tricolored zonal geraniums, the number of which are being constantly increased. Ought we not, then, in the formation of our shrubberies or plantations, to be governed to some extent by the striking examples afforded in the arrangement of our flower-garden decorations, and that by introducing those choice variegated trees and shrubs which can be readily purchased at our nurseries? With these brief remarks I will describe several of those varieties which I have selected for planting this autumn. Of course, large plants of many of the sorts are not obtainable, owing partly to their recent introduction, and the demand there is for them. We must expect years to

elapse before the markets will be overstocked with such varieties as I shall here enumerate.

Acer negundo variegatum (a deciduous tree).—When full grown it is said to attain the height of twenty feet. Without any exaggeration, it is the most striking tree I ever saw; any description of mine is imperfect as regards its beauty. Its silvery foliage is sure to arrest your attention even in the distance. Wherever sombre-looking trees abound and this is intermixed with them, it is sure to afford a bold relief.

Ligustrum vulgare variegatum (evergreen).—This is a variegated variety of the common Privet. The broad margin of bright gold which surrounds the leaf is very effective. No doubt ere a few years have passed away this will be so far increased as to induce some persons to plant hedges of it, and a fine sight such will afford, especially on bright sunny days.

Weigelia rosea variegata (deciduous).—This is a welcome acquisition as a variegated plant. Should it prove as valuable as the plain-leaved variety, *W. rosea*, for forcing in pots, it will be a great acquisition to the list of early forced plants.

Populus argentea vera (the Silver Poplar).—Who would not strive to diversify the character of the scenery, where rapid-growing trees are desirable, when we are enabled to obtain such beautiful objects, and of such quick growth as the silver poplar, its delicate white foliage presenting a grand relief to the green leaves of others of the same species?

Prunus padus acubasifolia (or spotted-leaved Bird Cherry).—Of all the singular but curiously spotted-leaved trees, this is one of the most curious. It is exceedingly attractive on account of the multitude of yellow spots which are thickly dotted over the leaves, the latter being as large as the well-known *acuba*, which render it the more conspicuous, especially as it attains a height of upwards of twenty feet.

Euonymus atropurpureus (deciduous).—The foliage of this plant is strangely tinted, its prominent colour being a dark purple during the latter months of the year. This is overlaid with patches of scarlet and light purple. It will make a very good tree for a second row or line, as it does not exceed six feet in height.

Castanea vesca variegata (the golden-leaved Spanish Chestnut).—There is something very bold and showy in the bright gold margin of the leaves, which will constitute it a very effective tree in whatever spot it may be planted. Its height is about ten feet.

Corylus Avellana purpurea (the purple-leaved Nut).—This is a variety of the common wood-nut, the foliage being in every way similar, except in colour, which is of a dark purple. The leaves may perhaps be rather larger than the common variety. Altogether it makes a very excellent addition to the list of deciduous coloured foliage trees.

Cornus mascula variegata (variegated Dogwood, deciduous).—This is an improvement in respect to the foliage, the leaves being margined with silver. The parent variety is a very rapid grower, though dwarf, seldom exceeding four feet in height; but it is a capital tree for planting as undergrowth in a shrubbery. The red bark of its wood produces a very striking effect intermingled with the green leaves of other shrubs.

Taxus baccata variegata (the Golden Yew).—It is not uncommon in large gardens, in our stroll through the country, to witness hedges formed entirely of yews, and many of them at least fifteen to twenty feet in height; but the golden portion of the foliage of the above variety is so strongly marked as to make it a very desirable evergreen for planting as a single specimen, it being very effective.

Chamaecyparis sphaeroidea variegata.—In making choice of this evergreen tree I was particularly interested with its elegant but graceful cypress-like appearance. The foliage being beautifully blotched with gold, it is well adapted for fulfilling the purposes recommended for the preceding.

Rhododendron Ponticum foliis auris (the variegated-leaved *Rhododendron*).—As regards the flower of this variety, it is no improvement on the old *Ponticum*, but its variegation is boldly defined, the green leaves being broadly edged with gold, which makes it very effective whether in the distance or the foreground. It is very hardy, for it was not injured in any way by the severe frosts of last winter. As most of our choice *Rhododendron* beds are planted near the residence, single plants of this variety, planted in the centre or ends of the beds, would tend to relieve them of that monotony which the dark green foliage of the other varieties present during the winter months.

Ilex aquifolium.—The Holly is familiar to individuals of every age, from its associations with one of our most festive seasons of the year; but it would be scarcely credited by those who are not familiar with the fact, that a tree that abounds so plentifully in our uncultivated woods and commons should embrace about one hundred varieties, consisting of plain green and gold and silver variegation, some of which are beautiful in the extreme, and conspicuous for their fruitful qualities, yielding berries of many colours. But in making choice of your sorts, and that you may the better appreciate their distinctness of character, your most advisable plan is to visit the nurseries where they are cultivated, and select for yourself.

Hedera (the Ivies).—Of these there are a vast number of varieties in cultivation, and very handsome many of them are, including all tints and shades of variegation. There are gold-leaved, silver-leaved, marble-leaved, notched-leaved, and finger-leaved varieties, and many of them yield yellow as well as black berries. Would not the several varieties present a very imposing and interesting appearance, if they were planted against some of our tall but clear-stemmed trees? No matter whether in the pleasure ground, the avenue, or the shrubbery, they would be equally effective.

Euonymus radicans variegatus.—The species and varieties of *Euonymus* are very striking and beautiful. There are several varieties, varying in height from one to eight feet; but the above variety does not exceed one foot in height. The green leaves are brightly margined with silver. It is first-rate as a variegated edging for large beds, and is quite hardy.

Vinca major elegantissima (the Silver Periwinkle).—This is a very desirable plant for a permanent dwarf bed. I saw a bed of it in full growth a fortnight ago, and the effect was fresh and striking, especially as the most of the bedding plants surrounding it had their beauty destroyed by the late frosts. Mr. Salter has a collection of about a dozen varieties of variegated Periwinkles. Jno. F. McElroy.

JONES wagged Brown that he had seen a horse galloping at a great speed and a dog sitting on his tail. It seems an impossible feat for a dog to accomplish, but Jones was right, and won the money. The dog was sitting on his own tail.

A SOLO IN PARTS.—Wilson, the celebrated vocalist, was upset one day in his carriage, near Edinburgh. A Scotch paper, after recording the accident, said, "We are happy to state that he was able to appear the following evening in three pieces!"

THE BEST OF THE ROSES OF 1867.

The best varieties for the past year—*i. e.*, introduced in the autumn of 1866, and grown and shown in 1867—are as follow:—

Antoine Ducher, H.P.—From Madamo Domago: bright red, large and full; very vigorous. Large but dull.

Bouton d'Or, Tea.—Bright deep yellow, small buds, little golden buttons, for the button-hole; from "Canari."

Charles Verdier, H.P.—From Victor Verdier, and somewhat of the same style and colour.

Comte Litta, H.P.—Purple and scarlet; one of a numerous line from Beaux Arts to Xavier Olibo; all more or less double.

Eugène Seribe, H.P.—Very brilliant bright red, also one of a numerous tribe.

François Treyve, H.P.—Dark, bright scarlet, double, "cabbage rose" form, vigorous habit.

Horace Vernet, H.P.—Another of the dark reds, with purple tinge.

Madame Margottin, Tea.—Pale citron yellow, centre tinged rosy peach.

Madlle. Annie Wood, H.P.—A fine flower, vigorous grower, colour bright clear red, large, full, and a decided acquisition.

Napoleon III.—Brilliant colour, scarlet and violet, in clusters.

Princess Mary of Cambridge, H.P. (Paul and Son).—Pale; an addition to a valuable line of colour.

Paul Verdier, H.P.—Bright rose.

Sœur Thècle.—Carmine rose.

Thorin.—Bright rose (by a first-rate raiser), very promising.

W. D. PRIOR.

OWN-ROOT ROSES.

My name is not Abel Hoyle, who was advertised for in a note from an excellent article by the Editor on the above subject, in the Magazine of Oct. 19; but I am glad to be able to supply some statistics of my own concerning the growing powers of rose-cuttings, in about fifty different varieties, which may in some degree furnish the supplement which the unfortunate loss or mislaying of the Editor's paper on the subject would have more ably supplied.

I give the results I have obtained in rather round numbers, feeling sure that they are sufficiently accurate for general purposes, and also that a change of locality, or even of position in the same garden, or the substitution of better for inferior cuttings, might have more widely altered those results, had they been supplied with the most scrupulous accuracy.

I divide these varieties mentioned in to four classes.

First, those roses whose cuttings yielded plants in a bed out of doors at the rate of 50 per cent. and upwards:—

Maréchal Suchet (Damaizin)	Aurore Boréale
Victor Verdier	Léopold I.
Madame C. Joigneaux	Gloire de Vitry
Dr. Andry	Abel Grand
Charles Lefebvre	Adolphe Noblet
Louis Odier	Vicomte Vigier
General Jacqueminot	John Hopper
Vainqueur de Goliath	Fanny Petzold
Jules Margottin	

Second class. Roses yielding about 30 to 35 per cent. of plants:—

Maréchal Vaillant	Goujon
Catherine Guillot	Baron Gonella
Anna de Diesbach	Duc de Rohan
Duchesse d'Orléans	Sœur des Anges
Alpaide de Rotalier	Madame Caillat
Maurice Bernardin	Sénateur Vaisse
Monsieur Boncenne	Madame C. Wood
Pierre Notting	Duchesse de Morny
Claude Million	Comtesse Chabriland

Third class. Names of roses whose cuttings yielded from 15 to 20 per cent. of plants:—

Madame V. Verdier	Madame Crapelet
Marguerite de St. Amand	Madame Boll
Sénateur Favro	

Fourth class. Bad doers, yielding less than 5 per cent.:—

Baron A. de Rothschild (none)	Lord Herbert
Madame de Cambacérès	George Prince
Duchesse de Caylus	Eugène Verdier
Xavier Olibo	Duchesse de Medina Cæli
Camille Bernardin	Jean Lambert
Mademoiselle Bonnaire (none)	Souvenir de W. Wood
Madame Vidot (one)	Lord Macaulay

These results are obtained from observations extending over two years, as regards many of the varieties named, the number of cuttings taken exceeding four thousand. I could add to the list, but think it unnecessary so to trespass on your space.

I may, however, add, that experiments made are full of interest, and experiments tabulated are very useful; and, taking a hint from the Editor's most practical remarks, I have this year started an experiment on rose cuttings placed under seven different circumstances, and shall be glad, if we live to another season, to state the results established thereby.

When own-root roses are well started, they are less liable to damage from frost than budded roses; but last winter I lost by far the most from amongst the rooted cuttings of 1865

(autumn), which were planted out in November, 1866, more so than from any other bed of roses on briars or manetti stock.

In full corroboration of the Editor's experience, and in full refutation of those who discredit the method he has adopted, and kindly recommended and published, I can add that I have gathered roses in the summer from cuttings made the previous October, and have exhibited them in winning stands against no mean competition; and what one has done others may also do.

EDWARD N. PECHIN.

Sibley Vicarage, Loughborough, Oct. 29, 1867.

A LESSON IN POULTRY KEEPING.

The truth is, that only a trifling portion of what poultry eat at a farm homestead involves any outlay, the birds picking up off the ground and redeeming from waste probably one half of their living; while the greatest proportion of the other half consists of the tail and refuse corn, which is only of nominal value. I am speaking of course of ordinary cases, where fattening heavy and early birds is not made a regular business, to which other departments of farm management have to give place. I know, for instance, of a yard where the mistress sells over £20 worth of eggs, beside furnishing a plentiful house consumption, raising pullets for keeping up her stock of one hundred hens, and feeding a few birds for her own table. The purchased food costs but a few shillings per year; the collection of eggs being the chief expense. I could name another yard where, for years, the proceeds from a brood stock of sixteen cross-bred hens with two cocks, and six ordinary brown ducks with one drake, have been over £25 per annum, in addition to the household supply of birds and eggs; no food bought excepting a few pounds' weight of chicken rice, only a few eggs sold, and the birds disposed of at the country market price of 2s. 6d. to 3s. 6d., and occasionally 4s. 6d. per couple. The henwife has been paid one-third of the gross receipts; but if the farmer's wife herself attended to the fowls, of course this deduction would all be saved.

A good profit may be made by the farmer's wife when selling eggs and birds at common market prices; and though the total income from this source may not be very large, yet it is too important to be sacrificed for lack of a little wholesome interest and attention.

The floor is not so well of brick or stone slabs as of earth, well rammed down and covered with loose gravel. This is to avoid harbouring the great pests of the henhouse, fleas. Dimensions will be very much matters of fancy, but shun overcrowding. Architects often plan roosting houses with perches one higher than another, rising like a ladder from floor to ceiling, taking care that one is not placed directly over another, as in that case the droppings of the upper row would fall upon the birds below. But all lofty perches are objectionable; heavy fowls injure their feet in jumping down; for though they will fly up or walk up a ladder to bed, they will generally take the shortest cut down in the morning. The best plan is to have perches all on a level, 2 to 2½ ft. from the ground; the best perch being a wooden bar of 3 or 4 in. in breadth; and if supported by legs like a stool, so as to be readily moved, so much the better. Clumsy birds like Cochins prefer a roost at even lower elevation, unless a very easy ascent is prepared for them. It is not necessary to have a separate house for laying, provided the nests be at the side, far enough from the perches. But a sitting-house should be prepared, in order that the sitting hens may not be disturbed by the other fowls. I need scarcely urge the importance of cleaning out the houses, say twice a-week, and of once or twice in the summer cleaning and limewashing the whole of the interior. Various notions are seen in the matter of nests. Some poultry-keepers have a number of wooden cells, like pigeon-holes on a large scale, with a hinged flap or door, or a slide, in front to fasten in unsteady sitters and to keep out intruders. The nests in my own hen-house are simply rectangular cells made of board 20 in. high, and 18 to 20 in. long and broad, set upon the floor and close to the wall—a bar running along the front edges of the boards, to keep the eggs from rolling out. But round shallow dishes of wicker are good; so also are shallow pans of earthenware half filled with sand; and some managers prefer simple cells of loosely laid bricks. As to the proper fibrous or other material for bottoming the nests, avoid long straw, for this is liable to pull eggs out of the nest by getting entangled about the hen's legs. Hay, again, is safer, but harbours abundance of vermin. The best materials are cocoa-nut refuse or short straw, dusted with flowers of sulphur to expel the fleas; while a sod with rough grass on it makes a good and moist foundation for all.

A common error is to coop successive broods in the same small enclosure, probably because this is near to the kitchen door, and convenient for the constant attention which is required. But separation is a main point in rearing healthy birds. Distribute your coops about your yards, of course choosing safe and sunny places; and if your early broods occupy a space before your house, you may put the later broods on a plot behind, and so on, always allowing a considerable interval to elapse before following upon the same ground, to avoid getting the walk "tainted," as it is termed, with liability to disease.—JOHN ALGERNON CLARKE, in *Science with Practice*, just published by Messrs. Longman and Co.

A CONE OF IRESINE HERBSTI.

Having first prepared and struck a lot of cuttings, a seed-pan of any desired diameter is got, together with a supply of light turfy peat, moss, and some strong wire. Having settled on the height, strands of wire sufficient to retain securely the material enclosed within them, when brought up longitudinally and secured to a point, so as to form the cone, are fixed to the seed-pan or base. The drainage is provided for in the usual way, and the pan is filled with rough peat, &c., to a level with the edge; then the little plants of *Iresine* are laid on the surface; over them a layer of peat and moss, then more plants, and so on till the cone is finished, when the whole is neatly mossed over, the wires brought into their places and secured at the point, and the work is complete. A tepid syringing gives the finish. It is introduced into the stove, where the plants have nothing to do but grow. They quickly lay hold of their quarters, and turn up their heads boldly, and soon the whole is a pyramid of beauty, and our plant becomes really valuable and highly decorative and ornamental. After standing in the house or conservatory, it may now be cut back, and introduced again into heat. It is only when grown in heat, we apprehend, that it is properly developed, or the peculiar beauty of its foliage fully brought out.—*Irish Farmer's Gazette*.

REPORT ON TRIAL CULTURE OF PEAS AT STOKE NEWINGTON, 1867.

The trial of peas at Stoke Newington in the past season was limited to 100 varieties, which were selected for the purpose, and were all sown on the 23rd of February. The ground was prepared by deep trenching and liberal manuring, and the rows were placed eight to twelve feet asunder, a plan which favours full development by the free access of light and air to the plant, and, what is not less important in such a case as this, affords facilities for conveniently inspecting the rows at every stage of their growth. The intervening spaces are appropriated for other crops, and as the peas are removed the spaces they occupied are planted with celery, winter greens, or sown with turnips, coleworts, &c. The peas sown on the 23rd of February made a good start, but the untoward weather of March and April so thoroughly decimated them, that on the 1st of May the ground was almost as bare as a newly-ploughed field. A few rows were but little hurt, but generally speaking the plant was wholly destroyed, for in dozens of rows there was not a single plant left, and in many others only a few dotted at long intervals, like chance weeds that the hoo had missed. The few that remained were therefore destroyed, fresh drills were drawn, and on the 2nd of May the collection was sown again. Unfortunately, in the first sowing the entire samples of several sorts were sown, so that at the second sowing a few important varieties were *non est*. The loss was, however, not of great consequence as matter for regret, except in one case, namely, the fine pea called "Newington Wonder," figured at page 440, in the report of last year. At one time it appeared that this variety was utterly lost; but three plants were discovered, the sole remnants of a run of about 200 feet, and these were watched, and a few pods of seeds were saved where-

time they began to afford distinct characters of bloom and pod to the time when it became necessary to destroy them, when their productiveness was past. The report will show the period from blooming to gathering in the number of days in every case; the date of sowing is never taken at Stoke Newington, for the simple reason that it is of no use. In respect of dates, there are but three that are of any importance in a business of this kind—the date of sowing, date of first gathering, and date when the variety ceased to be useful. It will be observed that the period from sowing to gathering is in every case shorter than in former trials; this is owing to the advanced state of the season when the seeds were sown, a rapid growth ensuing immediately afterwards. The samples for this trial were obtained from Mr. W. Clark, of 42, Bishopsgate Street Without, except in those cases where it was thought desirable to apply to the raisers or their appointed agents.

FIRST CROP (syn. *Ringleader*, supplied by Messrs. Carter and Co. and Messrs. Sutton and Sons), sown May 2, first gathered July 1, *period* 61 days. The earliest pea known, and having the peculiarity of giving the whole yield of its pods at once, its time of bearing extending only from 7 to 9 days. Thus the plant can be cleared off, and the ground be again planted with another crop while the season is not yet too far advanced for securing a free growth.

DICKSON'S FIRST AND BEST (F. and A. Dickson and Son, Chester), sown May 2, first gathering July 3, *period* 63 days. A compact, wiry-habited, free-bearing pea, which continues in bearing 9 to 12 days.

DILLISTONE'S EARLY (Dillistone), sown May 2, first gathering July 9, *period* 69 days. This sample resembled in all its characters Sangster's No. 1, yet could not be resolved into that variety, being more leafy in habit, less prolific of pods, and more robust in growth.

Lord Palmerston.

Smythies' Prolific.

Peabody.

Duke of Edinburgh.

with once more to raise a stock. The result of the second sowing was eminently satisfactory, the varieties all grew freely, and bore well according to their several qualities; there was not a particle of mildew or blight; and generally speaking most of the samples continued in bearing longer than ordinary, the result of beneficial rains when they were for the most part in full bearing. As in the trials of 1865 and 1866, many important and interesting points arose in the comparison of the varieties, as the report will show, and the decisions of the Fruit and Vegetable Committee of the Royal Horticultural Society were found to be erroneous in several instances, and especially in the case of a fine pea called Stuart and Mein's Early, which the committee pronounced to be identical with Dickson's Early Favourite, but which is in truth far superior to that variety, and so different in growth and habit as to be distinguishable from the other by the most casual observation. As to the question of the identity of First Crop and Dillistone's Early, it would seem desirable to ignore the second altogether, or rather, to extinguish the name, and refuse it any further recognition. Half a dozen different sorts at least are sold under this name, and one of the most plentiful forms of it is simply a bad stock of Sangster's No. 1. Certainly Mr. Dillistone has for many years past sent out in this name a pea which is much more like Sangster's than like First Crop; and if First Crop is a revival or restoration of the original form of Dillistone's Early, the new name is better than the old one, for it has but one meaning, whereas Dillistone's Early has come to mean almost anything, so that no one knows when ordering seeds what sort of pea will be sent under that name. We propose therefore to cancel the name, and henceforth we shall know no more of it; for if a name does not direct us to the thing it is supposed to signify, the name is a deception, and as a catalogue and garden designation "Dillistone's Early Pea" may be fairly considered a myth.

The trial peas of 1867 were inspected twice a week, or oftener, from the

TABER'S PERFECTION (G. Gibbs and Co. and Barr and Sugden), sown May 2, first gathering July 5, *period* 65 days. The growth was irregular, but in general habit and mode of bearing this variety most nearly resembles Dickson's First and Best. It is, however, a quite distinct pea, making a larger quantity of straw than any other variety equally early, and producing a good crop of well filled-pods. This is an excellent market pea, but is less desirable for the garden, as it is four days later than first crop, and a number of varieties come in with it. Nevertheless in every garden where the earliest peas are valued, this variety should have a fair trial. To the market grower it is important for its hardiness, earliness, fruitfulness, and the comparatively large amount of straw left when the crop is cleared off—a matter of some consequence where horses are kept.

PRINCE ALBERT (Carter and Co.), sown May 2, first gathering July 8, *period* 68 days. This was sown in order to compare one of the best representatives (which it is) of the old race of earliest peas, of which Early Kent and Early May are examples, with First Crop, Taber's, and other candidates for the first place in the order of supply. It is a good variety of its kind, but possesses no special qualification for esteem.

CARPENTER'S EXPRESS (W. Clark), sown May 2, first gathering July 7, *period* 67 days. As bad as last year—if possible, worse. A quite worthless and very much mixed variety; strictly speaking, it is not a variety at all, and, with Dillistone's, should be cancelled.

DUNNETT'S EARLY (Carter and Co.), sown May 2, gathered July 8, *period* 68 days. Not distinguishable from Early Frame.

EARLY FRAME (W. Clark), sown May 2, gathered July 8, *period* 68 days. A leafy, robust, but scarcely prolific variety. Now that First Crop and Dickson's First are established, we may dispense with Early Frame. But it must not be forgotten that it has rendered long service, and is still a good pea, though superseded by improved varieties.

WHEELER'S FIRST (Wheeler and Sons), sown May 2, gathered July 8, *period* 68 days. In character intermediate between First Crop and Sangster's No. 1; a good useful variety, evenly covered with pods of a fair size, considering its earliness.

POYNTER'S EARLY (W. Clark), sown May 2, gathered July 8, *period* 68 days. Identical with Early Frame, and therefore may be cancelled. It is a curious circumstance that several first-class London houses have given prominence to this variety in their seed-lists—a proof that catalogue descriptions are to be taken *eum grano salis*. It is much to be regretted that respectable houses should recommend a thing of this sort in entire ignorance of its value or genuineness.

SANGSTER'S No. 1 (W. Clark), sown May 2, gathered July 8, *period* 68 days. An excellent pea, more fruitful than the majority of those that come in at the same time, and admirably adapted to sow at the same time as First Crop or Dickson's Best, to afford a succession and keep up the supply until *Advancer* and *Early Ringwood* come in to follow.

NUTTING'S No. 1 (Nutting and Sons), sown May 2, gathered July 8, *period* 68 days. Growth very dwarf, barely reaching 15 inches; leaves dark green, pods containing an average of six peas each; the flavour excellent. This variety is distinct, but scarcely useful. It may indeed prove to be good for pot and frame culture, being of such excellent quality and so dwarf in growth, but as a pea for the open ground it is quite surpassed by others that come in at the same time.

EARLY EMPEROR (W. Clark), sown May 2, gathered July 12, *period* 72 days. This good old pea behaved remarkably well in the present trial, being covered with large pods from top to bottom, and lasting in bearing 25 days. It is a question, however, whether it is worth a place in the select list, now that we have several finer sorts equally early and scarcely less prolific. In respect of fruitfulness, however, the *Early Emperor* stands almost alone among second early peas, and no doubt will continue in favour with many cultivators for some years to come.

PIERPOINT'S No. 1 (Pierpoint, Warrington), sown May 2, gathered July 3, *period* 63 days. Not distinguishable from *Dickson's Best*, except that it is not so good a cropper, and the growth is very irregular.

ADVANCEE (W. Clark), sown May 2, gathered July 12, *period* 72 days. This early, fruitful, elegant, and delicious pea has but one fault, that of a tender constitution. In growth and every quality, except relative hardness, it is unequalled.

NUTTING'S DWARF EARLY (Nutting and Sons), sown May 2, gathered July 6, *period* 66 days. This very closely resembles *Nutting's No. 1*, but is in many respects for ordinary purposes a better pea. It grows one foot high, is robust and leafy, a good cropper, producing a large pod, which contains on an average six large peas, which when cooked are tender, buttery, and sweet. An excellent dwarf variety, lasting about 15 days.

BISHOP'S LONG POD (W. Clark), sown May 2, gathered July 14, *period* 74 days. This hardy, dwarf, prolific pea is admirably adapted for market culture as a second early variety, and is a good sort for cottage gardens and allotment grounds. But it is not a gentleman's pea, and therefore is not desirable for ordinary garden purposes.

STUART AND MEIN'S IMPROVED EARLY (Stuart and Mein), sown May 2, gathered July 15, *period* 75 days. This is pronounced by the Royal Horticultural Society's Committee to be identical with *Dickson's Early Favourite*, which is an error. It is true it is in some respects like the variety in which the committee propose to merge it, but it differs in its pale green colour (like *Ringwood*) and more leafy habit, in its larger pods, which are long and narrow, and contain an average of six to nine peas each. The height is four feet. This is a first-rate second early pea, quite distinct and eminently desirable. There can be no doubt that its handsome pods and fruitfulness will render it a first-class market pea.

RINGWOOD EARLY (W. Clark), sown May 2, gathered July 10, *period* 70 days. This good old pea is the type of an interesting class, and well deserves the high place it has long had in the lists of the best varieties. It bears abundantly, and possesses the desirable qualities of good colour and good flavour when cooked. It is typical in its pale colour, hardy constitution, and distinct characters of bloom and pod.

DALE'S EARLY (Thompson), the same in every respect as *Ringwood Early*.

ELEY'S ESSEX RIVAL (Eley), sown May 2, gathered July 10, *period* 70 days. The best variety of the *Ringwood* section, and deserving of a place in the routine of every garden. That it is distinct from *Ringwood* cannot be doubted by those who have made critical observations on both varieties in all their stages of growth, and in all the points of difference this variety is the best of the two. There can be nothing better than a dish of this pea well cooked, and it is but nine days later than *First Crop*, and is two days in advance of *Advancer*.

TAYLOR'S UNKNOWN (Taylor), received from Mr. G. Taylor, of Stamford Hill. It proved to be *Eley's Essex Rival*.

LORD PALMERSTON (Pierpoint), sown May 2, gathered July 27, *period* 87 days. This is a new pea, raised by Mr. Knight, of Battle. It is a mistake of the *Chiswick* report for 1867 to pronounce this the same as *Veitch's Perfection*, for though it produces a large pod, and the peas are excellent in quality, it is a poor cropper, and, as compared with *Veitch's Perfection*, worthless.

DICKSON'S FAVOURITE (F. and A. Dickson and Son), sown May 2, gathered July 20, *period* 80 days. A very prolific pea, of second quality; height 4 feet.

AUVERGNE (Sutton and Sons), sown May 2, gathered July 14, *period* 74 days. This productive and handsome pea will doubtless keep a place in the select list for many years to come, though in point of quality there are better varieties equally early. The pods are long, narrow, and curved at the point, and well filled with whitish peas. The average height of the plant is 6 feet.

LAXTON'S PROLIFIC (Carter and Co.), sown May 2, gathered July 17, *period* 77 days. In our report last year we pointed to the close resemblance this variety bears to *Auvergne*, but directed attention to the distinctions observable in the seed, that of *Auvergne* being very pale olive or buff, while the seed of *Laxton's* is a more decided tint of olive, or a dull almost dirty buff. It appears to be not generally known that hitherto *Laxton's Prolific* consists of two varieties, equally distinguishable in the seed-bag and on the ground. The seeds may be sorted into two distinct classes, olive and brown, and the plants may be divided into those which produce long *Auvergne*-like pods, and those which produce shorter pods. If the variety could be so far purified as to remove from it the short-podded plants, *Laxton's Prolific* would become immediately one of the finest peas in cultivation; but its mixed condition is a serious objection to it at present.

MACLEAN'S LITTLE GEM (W. Clark), sown May 2, gathered July 6, *period*

66 days. This is quite a failure at *Stoke Newington*, though on lighter and warmer soils it is a good cropper, and produces large pods of excellent quality. The dwarfest kinds of peas never attain to such perfection here as in more favoured localities.

TOM THUMB (W. Clark), sown May 2, gathered July 6, *period* 66 days. Quite worthless here, except for pot culture.

BECK'S GEM (W. Clark), sown May 2, gathered July 12, *period* 72 days. This sample was quite distinct from *Tom Thumb*, and in every respect far superior to that variety. *Tom Thumb* grows only six inches high here, but *Beck's Gem* grows 18 inches, and bears plentifully. Nevertheless we have many better peas in use at the same time, and though this is a good member of the class to which it belongs, it is of little value for garden purposes.

PEABODY (Carter and Co.), sown May 2, gathered July 4, *period* 64 days. A compact-growing pea of the white Prussian class, height 18 inches, bearing a considerable number of pods for so dwarf a grower; the pods well filled. A good and distinct pea of its kind, but scarcely deserving a place in any garden.

DWARF WATERLOO (Carter and Co.), sown May 2, gathered July 17, *period* 67 days. This is one of the best dwarf-growing varieties, and quite supersedes *Bishop's Long-pod*. The plant grows 18 inches high, and is quite covered with large pods, which are well filled with large peas of excellent quality.

DUKE OF EDINBURGH (Pierpoint), sown May 2, gathered Aug. 1, *period* 92 days. A dwarf, robust-growing, wrinkled marrow; the plant 18 inches high, very leafy and highly promising in appearance, yet failing to realize its promise in a crop. In a row 66 feet in length we did not succeed in obtaining a pint of good pods, yet abundance of pods were half formed and perished ere attaining maturity. On a different soil this may prove first-class; and although useless here, and a mockery, we do not consider our trial of it at all decisive as to its merits.

SMYTHIES' PROLIFIC (Barr and Sugden), sown May 2, gathered July 29, *period* 89 days. This variety grew 2 feet high, and bore an abundance of large pods well filled with large peas of good flavour. It was carefully compared with all other varieties of similar habit on the ground, and was found to resemble nearest *Veitch's Perfection*, but is not identical with that variety, or with *Premier*, which is the next nearest to it. *Smythies' Prolific* is a good variety, but has no distinguishing qualities of sufficient importance to entitle it to a place in the most select list.

VEITCH'S PERFECTION (W. Clark), sown May 2, gathered July 28, *period* 90 days. This popular variety is one of the most constant in its characters, the growth being so even that a well-kept row has the appearance of a freshly-clipped hedge. It produces an abundance of large pods, which are well filled with peas of the finest character. Height 2 feet.

HAIR'S DWARF MAMMOTH (W. Clark), sown May 2, gathered July 28, *period* 90 days. This variety grew 3 feet high, and gave a less abundant crop than *Veitch's Perfection*. We may now consider it a second-class pea.

THE PRINCE (Stuart and Mein), sown May 2, gathered July 30, *period* 92 days. The growth of this pea is extremely uniform, the height rather over 3 feet, the crop considerable and of the finest quality. The foregoing four varieties stood side by side, and were frequently noted in respect of behaviour and appearance.

Veitch's Perfection is a lighter colour (leaf, stem, pod, &c.) than either *Hair's Dwarf*, or the *Prince*.

Smythies' Prolific does not generally fill so well as *Veitch's Perfection*, but it requires a careful comparison to determine the difference between them.

The *Prince* resembles *Hair's Dwarf* more than *Veitch's Perfection*, but grows a trifle taller than either, is two to four days later, and, all points considered, the best of this series of dwarf-growing green wrinkled marrows.

S. H.

(To be continued.)

THE BEST ROSES IN GROUPS.

Most people who set about planting that very essential element of a garden, a rose-bed, would like to secure for it the best roses of the prevailing tints of colour, and accordingly their first proceeding is to send for a catalogue from one of the leading nurserymen, and plunge into the intricacies of the descriptions of the four or five hundred roses specified. The result is not always satisfactory. Let us, therefore, the present time being very opportune for sending out orders, try and make a few selections of groups likely to suit inquirers.

GROUP No. 1.—*Anna Alexieff*, fresh rosy pink, very free flowering, elegant foliage. *General Jacqueminot*, rich scarlet crimson, also very free flowering; too well known to need recommendation. *Emotion* (a Bourbon perpetual), white with a pink centre, also free flowering. *Charles Lefebvre*, dark velvet scarlet, shaded with black towards the bottom of the petals; this is in all respects the best rose grown. *Princess Mary of Cambridge*, a most excellent globular pink blush, very different to *Anna Alexieff* in form and colour. *John Hopper*, intensely bright light crimson centre, graduating towards the outside petals to a lilac pink. This group will do anywhere with ordinary attention and cultivation.

GROUP No. 2.—*Alfred Colomb*, true crimson, with every good quality; form particularly lovely. *Souvenir de la Malmaison* (Bourbon, but always in bloom), externally white, flesh-coloured centre; this is the finest light rose known. *Madame Moreau*, a lustrous dark crimson, with petals curiously folded, velvety and effective. *Gloire de Dijon*, yellow buff and pink, everywhere cultivated, or at least it ought to be. *Madame Victor Verdier*, cerise crimson, with the faintest tint of violet; a noble rose. *Comtesse de Chabrilant*, light pink; one of the most perfect of roses, if highly manured and properly attended to. N.B. This group consists of magnificent large roses, which require only to be seen to be highly admired, and, like most other good things, they demand good cultivation, which means good *stiff* loam, strong manure, and careful planting, and that surely is not asking for much.

GROUP No. 3.—*Duchesse de Morny*, true rose colour, the finest and most stately of its colour. *Prince Canille de Rohan*, maroon and scarlet; very fine in all respects. *Marguerite de St. Amand*, light pink, centre a little more intense, probably the finest light rose after *Souvenir de la Malmaison*. *Maurice Bernardin*, scarlet, with a faint tinge of violet; lovely colour. *William Griffiths*, glossy pink; an old rose; but not likely to be excelled; but, N.B., order this specially on a dwarf briar. *Pierre Notting*, dark crimson, deeply shaded with violet, a noble globular flower. This group also requires high cultivation.

These three groups are sure to please most people, and arranged in three separate beds will afford a feast of flowers.

VIATOR.

DESIGNS FOR STRAWBERRY HOUSES.

Early-forced strawberries are in such great request in every well-ordered garden, that we can only wonder that we so seldom see properly-constructed houses in which to grow them; and, knowing the universal want of such suitable structures, I here give some sketches of various forms of houses specially adapted for such a purpose, the first essential being to secure the plants abundance of light. But, before I refer more particularly to them, it may be well, perhaps, to set forth some of the conditions which must be secured to ensure the well-doing of the plants, and then the reader will the better understand the principles which have guided me in designing the plans.

In the first place, to force strawberries satisfactorily in the early months of the year, they must have all the light it is possible to give them, and they must be near the glass, else they will be drawn and weakly; and they must have also a

Fig. 1.

free circulation of air around them. Now these are conditions which every practical reader knows to be essential; and he also knows that, in the majority of cases, it is impossible to secure them to all the plants in old-fashioned houses, or in houses constructed differently from those shown.

In designing the sections here given, I have made the fullest possible exposure to light the leading feature, as the reader will see at a glance; and I am satisfied, from my experience in forcing strawberries, that more suitable forms than Figures 1 and 2 cannot possibly be made.

Figure 1 is a lean-to, with a shelf on the front and back wall, and three shelves suspended from the rafters. Ventilation is provided for by a ventilator in the front wall, and one at the junction of roof and wall below the plate. A service of four four-inch hot-water pipes is shown opposite the ventilator in the front wall. It is necessary so to place the pipes in front of the ventilator, because, when air is admitted, it comes im-

Fig. 3.

mediately in contact with the hot-water pipes, and so becomes heated before reaching the plants. The only objection that can be raised against this form of house is the weight of the suspended shelves. But by using deeper rafters, and if necessary a neat iron support from the floor to the rafter, as shown, nothing can be more easy than to make the roof capable of bearing any amount of weight with but little extra cost, if done at the outset.

Figure 2 is a hipped roof, and a very desirable form of house where strawberries are largely forced. A front sash should be provided above the ventilator in the front wall. This design does not greatly differ from the preceding, as the service of pipes and ventilation is the same in front, with means provided for giving air at the top.

Figure 3 is a span-roofed house, well adapted for the cultivator who does not begin to force until the middle of January,

and then it would be useful for many other purposes, and prove a serviceable house, too, when not required for strawberries. The shelves here are intended to be formed by a stage, and the ventilators and pipes are placed the same as in the above. A front sash over the ventilator would be desirable, the same as in Figure 2.

Figure 4 is an ordinary brick pit, fitted with a stage and a flow and return hot-water pipe in front beneath. Good strawberries may be grown in this structure during the latter part of March and through the month of April, and, as the lights are movable, the operation of watering is easily performed.

Figures 1, 2, and 3 are supposed to be furnished with fixed roofs, and the watering must be accomplished from inside, just as in any other case where top shelves are used.

J. C. CLARKE.

Fig. 2.

CULTURE OF CAMPYLOBOTRYS REFULGENS.

This plant thrives well in a compost of turfy loam and peat in equal parts, not sifting, but chopping the compost (which cannot be too turfy) fine with a spade, and adding to it one fourth of silver sand. Give a good drainage, and use a small pot. Water sparingly, place the plant in a moist atmosphere, at a temperature of from 65° to 70° at night, and from 80° to 90° by day, affording a slight shade from sun. Avoid wetting the foliage, and when the plant commences to grow and the pot is filled with roots, shift the plant into another pot, giving a large shift. The same compost and treatment as before are required, and afford a more plentiful supply of water. When the plant is growing freely, a moist atmosphere is beneficial. No moisture to be allowed over the foliage, plenty of heat and a position near the glass, with a slight shade from bright sun. These are the conditions for producing a fine specimen.

W. G.

Fig. 4.

EXPERIMENTS WITH POTATOES.

Dr. Hexamer, of Newcastle, New York, furnishes us with an account of some experiments of his with potatoes. We should preface the specifications of these results by stating that Dr. Hexamer is an accurate and scientific experimenter and observer, and a good farmer.

1. Out of seventy hills of potatoes, peeled so that no eyes were visible, thirty-five grew. Some produced very large potatoes. The planted potatoes remained, mostly, hard and firm till digging time.
2. Out of eighty hills, pieces cut without eyes, thirteen hills grew. All these sprouted on the cut surface, none through the skin. (One large potato, cut in two lengthwise, sprouted on the cut side near, but below the skin, and there was no sprout proceeding from a visible eye.)
3. Out of one hundred whole potatoes, ninety-eight grew from the small end, and two at the side. With more than half the number of potatoes planted whole, only one eye grew, the rest remaining dormant.
4. A potato does not always expend all germinating power in one year.
5. Wet rot and dry rot are one and the same disease. Potatoes affected with the rot will rot dry when they are kept dry, and the same will rot wet when they are kept in a moist place.—*American Agriculturist*.

Calendar.

WORK FOR WEEK COMMENCING NOVEMBER 9.

Kitchen Garden and Frame Ground.

ASPARAGUS beds to be cleaned over, the weeds raked off, and a heavy coating of half-rotten dung laid on, over which throw a sprinkling of earth from the alleys.

SEAKALE may be planted now in well-prepared ground in well-drained positions; where the soil lies low or damp, however, it should not be planted till the spring. In any case, the ground must be deeply trenched and liberally manured, and the manure thoroughly incorporated with the soil. Begin forcing now by first covering the stools with conical mounds of sand or coal-ashes (not leaves, which spoil the flavour). Place the seakale pots over as many stools as are to be started now, and fill the spaces between and over the pots with a mixture of stable-dung that has been once turned, with leaves, straw, and other litter, beating it firm as you proceed, and leaving the whole smooth and tidy nine inches above the top of the pots.

SEAKALE IN POTS.—Where only small quantities of seakale are required, it may be forced very conveniently and cleanly in pots. Pot the roots singly in 24-sized pots, in a mixture of leaf-mould, rotten dung, and sandy loam, equal parts. Place the pots on the top of a brick flue or on a gentle hotbed, the bottom-heat not to exceed 60°. Invert over each pot another empty pot, stopping the hole of each with a piece of flat tile, or with a lump of clay. For those who have no convenience to force seakale in the open ground, Pascall's pots are invaluable.

Flower Garden.

AURICULAS, CARNATIONS, PICOTÉES, AND PANSIES in POTS to have air frequently, to prevent mildew; slight frosts will not hurt them so much as a confined and damp air: take off the lights in the morning, and keep them off till the sun is nearly quitting the frames, then shut up, and there will be enough warmth retained to counteract the frost without. In damp dull weather, tilt the lights only to admit a small current of air through, and at every opportunity when the weather is genial take the lights off, clear away dead leaves, gently stir the surface of the soil in the pots, and give a little water if needed.

PLANTING ON MOUNDS is beginning to be better understood, and more generally practised, and consequently we less frequently hear of losses among ornamental trees of delicate constitution. Not long since we had to advise on some trees of Wellingtonia in a suburban garden. They had been planted out on the lawn to form a group, and by sun and not slow degrees had lost all their freshness of colour, the lower branches and the tips of the new growth becoming browned during winter, so as to have a most unsightly appearance. Araucarias in the same style of planting were in a similar bad condition. We had them all lifted, the earth entirely shaken off the roots, and then replanted on mounds made up of yellow loam from Wanstead. The mounds were two feet high, the roots of the trees were carefully spread out, covered only just sufficient to hide them from the daylight, and then staked with three stakes, each placed at an angle, in the style in which soldiers stand their muskets in groups of three on parade. They are now pictures of health and beauty, and the mounds are hidden by their branches weeping to the ground. All choice conifers that require a dry soil, or that are in any way susceptible of the effects of damp, should be planted in this way, and with a little management their lower branches can be trained down so as to sweep the ground all round, and make pictures of them.

BEAUTIFUL DECIDUOUS TREES FOR SMALL GARDENS.—Alterations and improvements are now in progress in gardens, and it is the season for planting. The names and brief descriptions of a few beautiful deciduous trees may therefore be useful to some of our readers. The subject, indeed, has scarcely ever yet had proper attention during the annals of British horticulture. There are innumerable species and varieties of beautiful trees in the country, but their names and characters are scarcely known beyond the limits of a few botanic gardens and arboretums. It might be thought that nurserymen and landscape gardeners would bring some of these trees into note, but it happens that as a rule they propagate and plant certain classes of trees that make an effect quickly, and which can be sold at a cheap rate; and too often ignorance is in the way of improvement much more than hard trade calculations. The consequence is, that we see limes, spruces, and other commonplace trees planted abundantly without regard to the capabilities of the place. All these common trees are beautiful in their way, and we say nothing against them except that we do not wish them to stand always in the way of the diffusion of others that are distinct, interesting, various, and beautiful, and which merit attention if only to break up the monotony of our gardens and shrubberies. The Decodar cedar, most beautiful of trees, would never have become popular unless it had happened to be one of the quickest growing, easiest raised, and most adaptable of evergreens. The desire of proprietors to cover large extents of ground at the lowest possible figure discourages a landscape gardener who would introduce rare and beautiful subjects. However, let us leave the commercial matters to settle themselves while we devote ourselves to the pleasing task of calling attention to trees that are prominent for beauty, and that will be sure to meet with appreciation some day or other.—*Kaltruteria pinnatifida*. This pretty tree never attains to a great size. A pair now growing at Stoke Newington have been planted ten years, and their heads are now only six feet over, and they stand about seven feet high. The habit of the tree is very peculiar and elegant, the growth being diffused and light, the leaves are pinnated in the manner of the ash, but are a thousand times more graceful, the divisions being prettily notched, and the appearance of the tree feathery. In July or August long spikes of yellow flowers are produced, which for a short time add much to the beauty of the tree. It will grow in any soil, and is quite hardy.—*Liriodendron tulipifera*. The "Tulip tree" has a bold distinct habit, and a very peculiar leafage, the leaves appearing as if their points had been abruptly cut off. It is sometimes planted in avenues, and it may be put in the mixed borders, and by annual pruning be kept to the size of a bush.—*Pyrus spectabilis*. This is the grandest of all the "flowering trees;" it is as hardy as a wild crab, and improves with age, like good wine. The flowers completely smother the tree in spring; they are white, red, bluish, or a mixture of all three shades. The pure white variety is perhaps the best, though very scarce. But it matters not if the commonest variety is planted; there is nothing to beat it.—*Double-flowering peaches*. The double-flowering peach, called *Persica vulgaris flore sanguinea pleno*, is a grander tree than its elongated name would lead any one to suppose. The flowers are large crimson, and are produced in such abundance every spring as to make the tree look like a little

mountain of fire. This is the hardest of the series, of which there are several. The white-flowered variety is tender. They are all good trees to grow in pots for forcing.—*Liquidambar imberbe* is like a small maple, but gorgeously coloured in autumn, when the leaves die off a rich purplish red colour. Very often *L. styraciflua* is sent out for it, which is the substitution of a satyr for Hyperion, the last named having not much beauty.—*Catalpa syringæiflora* requires plenty of room, and is quite out of place in a small garden. But in a suitable spot there are few trees more grand in outline and characters. Its huge spreading head, its large handsome leaves, and its thousands of spikes of whitish lilac flowers, produced in July, are features that claim for the tree the characterization of "magnificent." It requires a deep loamy soil, and is quite hardy, though in hard winters much of the young wood is killed back.—*Small-leaved elms*. There are two exquisitely pretty elms suitable for the choicest gardens. They are called respectively *Ulmus viminalis* and *U. v. variegata*, the second being a variegated form of the first. They form dwarf pendulous bushes, very dense, and full of grace, with slender twiggy branches, and neat little birch-like leaves. Any lover of such things would be sure to find pleasure in them.—*Salix Americana pendula*. This, the so-called "American willow," is in reality a British species. When worked as a standard it forms one of the most elegant of all weeping trees. The head grows symmetrically, throwing out long whip-like arching shoots of a pale red, clothed with small bluish green leaves. For a *bijou* tree to plant beside a fountain, there is nothing better. It also makes a nice bush, but I have never seen it in nurseries in that form. However, those who want bushes, and can wait for them, may raise any quantity by putting in cuttings in winter; every cutting will root. I would undertake to raise enough from one tree to begin with, in the course of three years, to plant a hedge of it from London to York.—*Weeping poplar*. There is in the English nurseries a weeping tree which is scarcely known amongst collectors of such things, though it is the finest weeping-tree known. The name of it is *Populus canescens pendula*. The growth is so truly pendulous that a tall standard will produce branches that in a few years will touch the ground and form a sort of bell-tent of beautiful leafage. Another nearly, if not quite, as good is *Populus tremula pendula*, a variety of the aspen poplar. Any one wishing for a superb lawn tree, and having some aversion to the weeping ash (which is a true beauty, though London people get sick of it, because it is always planted in tavern gardens) may plant either of these with perfect safety. To regret the deed is possible only with a lover of pitchforks and corkscrews.—*Fern-leaved beech*. The variety of *Fagus sylvatica* called *heterophylla* has the leaves very finely and curiously divided. It is very pretty, and what beech is not?—*Silvery maple*. The well known *Acer pseudo-platanus foliis argentea* is the grandest of the variegated maples. It is well known, and is one of the few beautiful trees that happens to be thoroughly appreciated. For a fine big spreading tree to light up a plantation, nothing better.—*Snowy mespilus*. The small-growing round-headed *Amelanchier botryapium* is always neat and pretty. But see it in bloom, and say the snow falls when the sun shines, and trees wear white gloves, like judges who have nobody to hang. And that puts me in mind of the *Judas Tree*, which I grow as a bush six feet high, and six feet through. In the spring it is tasseled with rosy pink flowers all along the ripe wood, and for the rest of the summer it is like a gigantic specimen of *Adiantum reniforme*. Could anything be more splendid? Seeing is believing, at least with some people. "Veni, vidi, vici."—*Two choice thorns*. For a change plant *Crataegus Mexicana* and *C. orycantha pendula*. The first is a fine evergreen, glorious in leaf, flower, and fruit. The second is a "genuine" weeping thorn, full of grace and glory. The scarlet-flowered thorn, and the double scarlet-flowered thorns, and the pink and double white are essentials to any garden that can afford space for them.

Fruit Garden and Orchard House.

RASPBERRIES to have the old canes cut away, the new canes thinned to three or four of the strongest to each stool, and a good mulch of half-rotten dung laid down over their roots, and the ground between them not to be dug at all.

FRUIT-TREE SHRUBBERIES.—Fruit-trees of many kinds are admirably adapted to plant for the embellishment of the pleasure garden, and when so employed the formal orchard system of planting must be avoided. It would be necessary, in order to preserve the ornamental feature proper to a shrubbery, to select trees best adapted for beauty of effect. Old standard apple-trees in good condition are equal in beauty to oaks any day, and there are some varieties of pear, plum, and cherry that make remarkably handsome trees of large size. Thus, then, we shall have no trouble in selecting materials for breaking the sky-line, and affording some kind of majesty to the shrubbery. Nevertheless, pyramid and bush forms are those most needed to produce the thick and various plantation that affords so much delight during a walk through a shrubbery. A most important member, therefore, of this useful shrubbery is the filbert, which never becomes a great tree, which is usually picturesque, and, while in leaf, a very bold and handsome tree. It is not generally known that the purple-leaved nut, which is catalogued as one of the choicest garden trees, is also a really profitable variety to grow, for the nuts are produced in plenty, and are of excellent quality. The apple, plum, cherry, mulberry, quince, and pear may all be employed in the form of bushes and pyramids; and in respect of beauty the pear will undoubtedly take the lead, for leafage that almost equals the caucellia, for flowers that rival the may or the snowdrift, for fruit that is always elegant, and sometimes rich in colour. Moreover, a few peaches, apricots, and nectarines may be added, and in good seasons their fruits will ripen well, and in bad seasons they will be splendid when in flower, and their leafage equal in beauty to that of most shrubbery trees all the summer long. To vary the front lines we have the berberis, useful for preserving; the currant, a grand thing for ornament when grown in the standard form, four or five feet high; the gooseberry; the raspberry; and there might be an edging of strawberries to finish off with. You will be saying that this, after all, is a fruit garden. Well, so it is; but I am considering how this fruit-garden can be made to do its duty as shrubbery in gardens where fruit is valued, and where the owners are not wealthy enough to have orchard and shrubbery too. You see it compels us to consider the case, not alone as to the usefulness of certain fruits, but as to their ornamental qualities, those said ornamental qualities being but little or not at all thought of in the arrangement of an ordinary fruit garden. Let us begin, then, to plant a belt, and not a square. There may be, say, a walk in front of the belt, and on the other side of the walk a grass-plot or lawn. The belt is to be shrubbery, and there are available for it, in the way of trees, limes, poplars, willows, alders, &c., &c. Now I propose that we plant, instead, standard apples, pears, plums, cherries, one or two walnuts and mulberries; and, in the event of this border being in a very warm and highly-favoured part of Britain, a few standard sweet

almonds. Should larger trees be wanted for the background, the Devonshire Prolific chestnut would occasionally afford a crop of eatable nuts, and in time to come most valuable timber. For the bulk of the furniture, we must rely on bush and pyramid fruit-trees. If well managed, these are most beautiful and interesting, the pears especially, and they produce enormous crops, considering the comparatively small extent of ground required for even a large collection. I would mix a few evergreens, dwarf shrubs, and clumps of hollyhocks with them, to preserve the shrubby character, and I would afford ample room to all to allow of a free circulation of air, and admit abundance of light. The finishing of the front line would require more taste than the general arrangement of the mid-distance and background. A few Weigelias, scarlet-flowering Ribes, the golden-flowering Forsythia viridissima, Cotoneaster Simonsii, and any or all the hardy Berberis obtainable, would be suitable to obtain a pleasing variety; and with a few clumps of herbaceous Pæonies, Frits, Phloxes, and Achilleas would secure both interest and beauty. The useful part of the front line would, of course, consist of standard currants, trained gooseberries of the goblet and umbrella forms; Berberis vulgaris, miniature apple, pear, cherry, and plum trees; and a few of the hardier varieties of grapes, trained to stakes. Of course they will persist in growing large, but that only fits them for removal a stage further back. The last remark serves to introduce all I think it needful to say as to the cultivation of these trees. To buy and plant them is easy work enough, but to do full justice to them is another matter. Unless the soil is extra rich, the surface should be mulched every winter with half-decayed manure, two or three inches deep, and every tree not required to become a giant should be carefully lifted and replanted every second or third year. The labour required for this process will be more than paid for by the increased and increasing productiveness of the trees. And to reduce the treatment to system, the best rule to follow would be to lift and replant a portion every year; so that, in the course of every three years, all except the standards should be subjected to the process. During the summer the periodical pinching back of the shoots, until the latter part of June, would have to be attended to. Such a shrubbery, therefore, would afford recreative employment, as well as recreative sights, odours, and flavours; it would tend to promote perfect harmony between the heart, the head, and the hands. And the consideration of the subject is earnestly commended to all our amateur readers who cannot command both fruit gardens and shrubberies on so ample a scale as the scope of their desires.

A SHORT LIST OF HANDSOME VARIETIES OF USEFUL FRUITS.—APPLES.—
Dessert kinds, suitable to grow as Bushes and Pyramids.—Astrachan, White Calville, Cornish Gilliflower, Court Pendu-plat, Court of Wick, Cox's Orange Pippin, Dutch Mignonne, Early Julien, Golden Drop, Golden Pippin, Red Juneating, Kerry Pippin, Melon, Old Nonpareil, Irish Peach, Grange's Pearmain, Pearson's Plate, Quarrendon, Reinetto du Canada, Ribston Pippin, Northern Spy.—*Kitchen Apples for Bushes and Pyramids.*—Beauty of Kent, Bedfordshire Foundling, Cellini, Cox's Pomona, Duchess of Oldenburgh, Fearn's Pippin, Flander's Pippin, Gooseberry, London Pippin, Mère de Ménage, St. Sauveur, Waltham Abbey Seedling.—*Varieties that make fine Standards.*—Shepherd's Fame, K, D; Stamford Pippin, D; Franklin's Golden Pippin, D; Early Nonpareil, D; Isle of Wight Pippin, D; King of the Pippins, D; Cockle Pippin, D; Blenheim Orange, K (this makes a gigantic and noble tree in a free, deep, heavy loam); Keswick Codlin, K; Manx Codlin, K; Dumelow's Seedling, K; Hawthornden, K; London Pippin, K; Norfolk Beefing, K; Northern Greening, K; Warner's King, K.—**PEARS.**—*Varieties suitable to grow as Bushes and Pyramids.*—Alex. Bivort, Alex. Lambre, Baronne de Mello, Bergamotte d'Esperen, Beurré d'Aremberg, Beurré d'Amanlis, Beurré Diel, Easter Beurré, Beurré Hardy, Beurré Léon le Clerc, Colmar d'Ete, Comte de Lamy, Comte de Paris, Délices de Jodoigne, Conseiller de la Cour, Doyenné d'Ete, Forelle, Havshe's Victoria, Josephine de Malines, Louise Bonne of Jersey, Madame Miller, Winter Nelis, Yat.—*Varieties suitable to grow as Standards.*—Jargonelle, Zephirin Grégoire, Thompson's, Suffolk Thorn, Swan's Egg, Seckle, Knight's Monarch, Bon Chrétien, Comte de Flandres, Duchesse d'Orléans, Eyewood, Gansel's Seckle.—**PLUMS.**—*Varieties adapted to grow as Bushes and Pyramids.*—Coc's Golden Drop, Dennison's Superb Early Mirabelle, Golden Esperen, Green Gage, Guthrie's Aunt Ann, Jefferson, Reine Claude de Bavay, Belle de Septembre, K; Mirabelle, K; Mirabelle Tardive, K; Cluster Damson, K.—*Varieties adapted to form large Trees.*—Brahm's Green Gage, Huling's Superb, Kirke's, Mamelonne, Prune Pêche, Perdrigon, Violet Hatif, Transparent Gage, American Damson, K; Autumn Compote, K; Diamond, K; Gisborne's, K; Early Orléans, K; Pershore, K; Pond's Seedling, K; Victoria, K; Washington, K.—**CHERRIES.**—*For Bush Culture.*—Archduke, Belle de Choisy, Coc's Late Carnation, Belle Magnifique, Late Duke, Florence, May Duke, Morello, Reine Hortense.—*Suitable to form handsome Trees.*—Belle d'Orléans, Bigarreau Napoleon, Black Tartarian, Cleveland Bigarreau, Downton, Elton, Governor Wood, Archduke, Empress Eugénie, Kentish, Nouvelle Royale. Lists of other kinds are of less importance than the classes already considered. We have no handsomer shrubby trees than the American and Siberian crabs, but the pity is that very few people can turn their fruits to any good purpose. Yet they are well worth preserving. One method, practised in the writer's household, is to place them in jars quite dry, and pour boiling honey over them. In due time they are taken out, and used for open tarts, and are in this way delicious. Another good use for them is to make apple jelly. The little apples are stewed till quite soft, but are not allowed to break, in as much water as will just cover them. They are then strained off, and squeezed, and thrown away. The liquor is then boiled with sugar, at the rate of three-quarters of a pound of sugar to every pint of the juice. Flavouring may be added, if desirable, but a little lemon-peel and lemon-juice are all the flavourings required. After simmering half an hour, the liquor is poured into moulds, where it becomes a transparent jelly, of most delicate flavour and elegant appearance.

Greenhouse and Conservatory.

CINERARIAS have now their seasonal ordeal to pass through, and must have every proper attention, or mildew will eat them up. Sulphur them if there is the least sign of the plague, and give plenty of air. Get specimen plants into shape, and put the early ones into their blooming pots; stop ten days after shifting.

CAMELLIAS dropping their buds are the subject of frequent complaint at this time of year. We have frequently advised the use of liberal waterings after the buds are set and the wood as hard as necessary, and we can only repeat that in the majority of cases the buds drop because the roots are dry. But watering on the ordinary plan is not always a remedy, for while the plants were out of doors in the summer the soil about the roots may have got hard and impervious to water, and now when water is given it all runs away next the side of the pot without moistening the roots at all. The remedy is

easy enough. Fill a tub with soft water, to which add a quart or so of boiling water, to make the whole nearly tepid. Then lower the plants into it a few at a time, and let them soak for an hour. The rush of air bubbles from the pots will prove what a dry state the roots had come to. After this soaking they will take water kindly until they get their next baking, which we shall suppose will not take place till next summer again. We serve all hard-wooded plants this way that have been some time in the same pots, as it is next to impossible to prevent the occasional hardening of the earth about their roots, and this sometimes happens in winter when, owing to long-continued frost, water is withheld for a week or two.

FROZEN PLANTS.—The amateur must always bear in mind that plants kept dry and well aired can endure two or three degrees more frost than plants of the same kinds in a more damp condition. As with the best precautions valuable plants will sometimes get wholly or partially frozen, a word of advice now may be useful all the winter through. To recover frozen plants, the safest proceduro is to keep them in the dark till they thaw, and to let the thawing take place slowly. A dry still air is also essential; a frozen plant placed in a draught, in the sunshine, or in undue warmth, even if in darkness, will probably go to a pulp as soon as it is completely thawed; but if thawed slowly in dark and stillness, will recover, if the freezing has been only to a moderate degree. These remarks refer chiefly to half-hardy and greenhouse plants, such as geraniums, &c., &c., but they apply also to hardy plants when the frost catches them out of the ground, as, for instance, trees on their way from nurseries, if the roots get frozen they suffer much unless thawed in the dark, as advised for plants of more tender constitution.

Stove and Orchid House.

ORCHIDS of deciduous habit to have little or no water, and no more heat than will suffice to keep them in health. Plants in a growing state must have enough water to prevent exhaustion. Young specimens may be kept growing freely in the warmest part of the house.

Forcing Pit.

FORCING.—See former notes under this head, and any matters hitherto neglected proceed with as previously advised. Make it a rule never to push any plant too hastily, or to use more heat than will suffice for the object in view. None but a trade propagator ought to have a higher temperature than 65° in any house at this time of year.

Literature.

The Intellectual Observer for November contains an account of that beautiful tribe of oriental birds, the Barb-ts, by Dr. Sclater; an elaborate paper on the growth of the scales of fishes, by Jonathan Couch; a profusely illustrated essay on the grave-mounds of Derbyshire, by Mr. Jewitt; a paper by the renowned Quatrefages on annelids; and a number of original articles on microscopy, astronomy, and physics, by Mr. Slack, Niepce de St. Victor, Rev. T. W. Webb, and other scientific explorers.

The Floral World for November contains an article on the picturesque in garden scenes, with suggestions on laying out a pleasure ground; also papers on fruit prospects, new bedding plants, the growth of peaches and nectarines without the aid of walls or glass, the management of the kitchen garden, on bardy flowers of the year, weeping trees, &c., &c.

The Gardener for November contains a continuation of the able series on the flower garden, also papers on restricted vines, calceolarias, the chrysanthemum, greenhouse plants, the clematis, &c., &c.

The Journal of Botany for November contains papers on abnormal forms of Ophrys, polliniferous ovules in a rose, British mosses, plants collected in Norway and Lapland, and on the obstacles to the utilization of New-Zealand flax; the authors of the principal papers are Dr. Masters, J. T. Moggridge, Esq., Dr. A. Dickson, and Dr. Lauder Lindsay.

A Handbook of Vine and Fruit-tree Cultivation under Glass. By SAMUEL HEREMAN, of Chatsworth. 7, Pall Mall East.—This admirable work, by the patentee and manufacturer of Sir Joseph Paxton's patent hot-houses, has reached a third edition. We have on former occasions explained its purport and testified of its value, and have only to repeat now our hearty recommendation of it to the careful attention of all who are interested in the cultivation of fruits under glass. Mr. Hereman has added many useful matters to this acceptable brochure, not the least useful being lists of produce which may be obtained from gardens under glass, and varieties of vegetables and fruits best adapted for this kind of cultivation. One of these lists we transcribe in full, believing it may prove acceptable to many of our readers:—

PRODUCE WHICH MAY BE EXPECTED FROM A LARGE WINTER GARDEN.

JANUARY.—In addition to the ordinary supply of fruit and vegetables from the open air, we may have the following produce from the winter garden:—Of *Fruit*, apples and pears, grown either in pots or the orchard house borders; late grapes, still hanging on the vines; and cucumbers, pine-apples, and bananas, where portions of the house are extra heated and appropriated to these purposes. Of *Vegetables*, cauliflowers and broccoli laid in the border of the house, spinach sown in the border, mushrooms in the shed, rhubarb in the lower bed of the mushroom house, asparagus in the frame on a hotbed, lettuce and endive planted in the borders, sea-kale grown under pots with hot manure, and small salad sown in the borders of the house.

FEBRUARY.—The same fruit and vegetables will be supplied as in the last month, with the addition of early radishes and early cabbage.

MARCH.—*Fruit*: Apples, pears, late grapes, strawberries, pine-apples, and cucumbers. *Vegetables*: The same as last month, and kidney beans and early potatoes grown in pots, and early cabbage.

APRIL.—*Fruit*: Old apples and pears, early grapes, strawberries, peaches, nectarines, figs, cucumbers, pine-apples, and green gooseberries. *Vegetables*: Rhubarb, asparagus, mushrooms, potatoes, kidney beans, radishes, small salad, lettuce, and early cabbage.

MAY.—*Fruit*: Early grapes, strawberries, peaches, nectarines, apricots, plums, cherries, figs, cucumbers, melons, pines, gooseberries, currants, and raspberries. *Vegetables* will now begin to come in plentifully out of doors, so the ground will for the most part be cleared inside; however, mushrooms, kidney beans, and new potatoes will still be supplied from glass, and peas and beans.

JUNE.—*Fruit*: Grapes, peaches, nectarines, apricots, plums, cherries, figs, cucumbers, pine-apples, gooseberries, currants, raspberries, apples, pears, melons, and most other kinds of fruit. *Vegetables*: Mushrooms are now about the only crop requiring indoor culture.

JULY.—Fruit : Apples, pears, apricots, peaches, nectarines, late cherries, figs, melons, cucumbers, and grapes are the principal fruits inside ; the crops in the open air will now be generally fit for use. Vegetables : Except mushrooms, all kinds of vegetables are now abundant outside.

AUGUST.—Fruit : Every kind of fruit of the sea-on is now in perfection. Vegetables : All kinds are now in perfection in the open air.

SEPTEMBER.—Fruit and Vegetables of all kinds can now be supplied for table.

OCTOBER.—Fruit : In addition to the usual kinds of fruit ripe at this season of the year, strawberries are supplied in the winter garden from roots forced for early crops in spring, currants and gooseberries protected by mats, and Cape gooseberries.

NOVEMBER.—Fruit : Apples, pears, figs, melons, cucumbers, late strawberries, raspberries from double bearing canes, grapes, pines, bananas, Cape gooseberries, currants, and gooseberries, which have been kept back by matting and Eugenia Ugni. Vegetables : Mushrooms, cauliflowers brought into the winter garden borders, broccoli, late crop of kidney beans, late peas and beans, lettuce, endive, small salad, and radishes.

DECEMBER.—Fruit : Apples, pears, cucumbers, strawberries, grapes, pines, and bananas. Vegetables : Mushrooms, cauliflowers, broccoli, lettuce, endive, and small salad.

RECEIVED.—The Botanical Magazine, L'Illustration Horticole, The Ladies Treasury, Our Own Fireside, Country Life, The Watchmen of Ephraim, The Gospel Magazine and Protestant Beacon, Old Jonathan, River of Life Pilgrims.

Correspondence.

YAFFOL OR YAFFLE.—The bird referred to in page 473 is the Green Woodpecker, *Picus viridis*, Linnæus ; *Le Pic Verd*, Buffon. From tip of bill to end of tail, thirteen inches ; bill two inches long ; tongue barbed at point, and supplied with a glutinous matter, to which ants and their eggs adhere. It is capable of thrusting out the tongue three or four inches. The top of the head is crimson, the back and wing coverts olive green ; rump yellow ; quill-feathers dusky and barred on the outer web with white ; under part of the body white tinged with green ; tail marked with bars like the wings. It frequents ant-hills, from whence it obtains its principal food ; therefore it was wise of Mr. Clarke to spare its useful life. THOMAS BARNES, Taxidermist.

Petersfield. The common green Woodpecker, *Picus viridis*, is so called in the counties of Kent and Sussex from its curious alarm note. Underneath it is of a yellowish green, brownish wings, crimson feathers at the back of head and neck.

I don't know what sort of bird a "Yaffol" may be, but I should suppose it to be some ravenous sort of creature, for when I was a hungry boy, and a big pudding was placed before me, I used to be told to "yaffle it up." So I conclude a Yaffol or Yaffle is a bird that eats. Isn't that logic ? No mention of Yaffol in "White's Selborne." BOB.

I don't know what a "Yaffol" may be, but I fancy the bird which your correspondent, J. C. Clarke, describes to be the Green Woodpecker, *Picus viridis*. It is very common in this neighbourhood, and is called by the Welsh "Caseg-y-ddryghin," literally translated into English, "The bad weather Mare," the weather-wise supposing that rain is not far distant when the woodpecker is particularly noisy. CYMRA.

Peat Charcoal.—In "replies to queries" respecting Hays's Stoves, you say that the Company will not sell less than one ton of peat charcoal to any customer. We think that this is calculated to mislead your correspondents, as it is our intention to supply the Peat Charcoal by the bushel, but only the best quality, and we have already ordered a quantity to be delivered in London, and as soon as we can form an idea of the time when we shall be in a position to supply it, we shall give notice thereof by advertisement in your magazine. ELSAM AND CO.

38, Upper Thames Street.

Replies to Queries.

Plants to Grow under the Drip of Trees.—J. B.—The following bear the drip of trees well, and are excellent for ornamental planting in positions where most other things would fail for want of more free exposure: *Berberis aquifolium*, *Berberis Asiatica*, *Berberis Japonica* ; *Buxus sempervirens*, and all its varieties except *suffruticosa*, *Buxus Clinchensis* ; *Ligustrum Japonicum*, *Ligustrum lucidum*, *Ligustrum sempervirens*, and all the varieties of the common privet ; *Rubus discolor*, *Rubus radula*, *Rubus cæsius fol. var.*, *Rubus fruticosus floro pleno*, and all the varieties of the common bramble ; *Taxus Canadensis*, *Taxus bacata fol. var.*, and all the varieties of the common yew ; *Hypericum elatior*, *Hypericum calycinum*, *Hypericum kalmianum* ; *Cornus sanguinea*, *Cornus mascula variegata*, *Cornus sempervirens* ; *Juniperus communis* ; *Hollies* ; all the varieties of the common Ivy, *Periwinkle*, and *Tussack grass*.

Climbers for a West Wall.—J. B.—Japan Honeysuckle, *Cotonæster microphylla*, *Magnolia grandiflora*, in sheltered localities. *Roses* : *Félicité Perpétuelle*, *Renoneule*, and any *Noisettes*, *Ecere-mocarpus scabra* (should be renewed when seven years old). *Jasminum nudiflorum* ; *Passiflora azurea* (in warm places). *Solanum jasminoides* (in warm positions ; must be close pruned till it blooms freely) ; *Ceanothus azureus* ; *Fuchsia Riccartoni* (in sheltered positions, but will not stand a severe winter) ; *Periploca greca*.

Liliums for pot culture.—A. Macfarlane will find the following well worth cultivation in pots: *Auratum*, *colchicum*, *exelsum*, *oximium*, *lanefolium* (all the varieties), *longiflorum*, *Philadelphicum*, *tennifolium*, *Thomsonianum*.

24 Pinks.—A. Macfarlane.—The following are a fine lot ; grow them well and you may show them anywhere : *Attraction*, * *Beautiful*, *Brilliant*, *Charles Waterton*, * *Delicata*, *Dr. Maclean*, *Ellenor*, *Ernest*, *Eugene*, *Invincible*, *John Ball*, *Lord Herbert*, * *Lizzie*, *Mrs. Maclean*, *Picturata*, * *Rev. G. Jeans*, *Scarlet Gem*, * *Titians*. * For the benefit of readers who want six good pinks, we have marked the six we should prefer with asterisks.

Tyros.—We can only suppose that the roots of the vines are too wet in winter and too cold in summer.

D. A. G. B.—You have no legal right to remove your rose-trees ; they belong to the freehold. 2. Rose-stocks budded this season may be removed now without killing them, but it will be safer to wait another fortnight. 3. Sow rose-seeds as soon as thoroughly ripe in any good loamy soil.

A. B.—You send too many, and we will not name any.

Sewage Farming at Edinburgh.—C. P. P.—The following are the figures which Mr. King's paper, read last year before the Society of Engineers, gives as a summary of the extent of meadows thus irrigated near Edinburgh, with the returns from each in 1860 :—

	Quantities.			Price per acre.			Total amounts.		
	A.	R.	P.	£	s.	d.	£	s.	d.
Craigintinny Meadows.

In different lots	4	0	0	24	0	0	96	0	0
Total	347	1	36½	27	8	6½	9,529	17	4½

Mr. King remarks that "In carrying out the foregoing summary it must not be understood as representing the exact amount of money made in each individual case ; it is merely the averages, carefully taken, and probably approximating very near to the fact. In order to ascertain how near the averages approximate, the exact amount of money made by the roupings of three different parts of the Craigintinny Meadows was taken—namely, the Sea Meadows, the Fillieside east of burn, and the Burniwads Meadows—which amounted together to £1940 6s. 4½d. ; and the average amounts of those three portions, as will be seen by the table, is £1941 19s. 1½d. According to this result it may fairly be presumed that the averages will not be far from the facts. It appears, from the aforesaid summary, that the total quantity of land at present under irrigation with the town sewage, is 347a. 1r. 36½p."

Rosery Basket Plants.—R. K., Paignton.—The heavy loam will suit roses admirably, for such as do not thrive on their own roots in it will do well on briers. The admixture of coal-ashes will not injure the soil, but are not calculated to do any particular good. The proper way to prepare the soil for the rose is to trench it thoroughly, breaking it up to a depth of two feet, and laying it up in ridges for a month ; then to dig it over again, and at the same time put on a heavy dressing of good manure. Plenty of time for all this to be done well, and the roses may be planted in February. If you want a design, probably the frontispiece to the "Rose Book" may afford a suggestion. Basket plants to flower in winter are not numerous. First in rank of importance we must name the *Tropæolums*.

G. B. P., Cottingham.—The primulas raised from Messrs. F. and A. Smith's strain are peculiar and novel. They measure rather more than an inch and a half across, are elegantly fringed, and notched on the edge, the centre is green ; this changes to greenish brown, and then passes into rich rose-pink all round. As a rule, green in a flower is objectionable ; but it is likely, we think, that this particular form of primula may be highly ornamental.

Stoves for Small Plant-houses.—Subscriber.—The break-down in the supply of Hays's stove is a calamity. When that appeared, we supposed a great difficulty, that of effectually and safely keeping the frost out of small houses, was completely solved. But here we are again in the thick of it. In the GARDENER'S MAGAZINE of August 12, 1861, we published an account of Musgrave's Slow Combustion Stove, which is an admirable contrivance for this purpose, and one we can again recommend. It is, however, too powerful for the smallest plant-house ; but a house 20 to 30 feet by 7 to 9 feet (say) would be well kept through the winter by means of one of these placed in the centre. Musgrave's stove is fed with small coke, and if properly managed will burn 12 to 16 hours without attention, diffusing while it burns a kindly and quite wholesome warmth. Those who wish for further information are referred to Messrs. Musgrave Brothers, High Street, Belfast.

Empty Garden.—S. A. K.—An empty garden in the South of Devonshire may be quickly altered in its appearance by planting trees and shrubs, which may be done now, and the sooner the better. In the kitchen garden you may sow early peas and beans, such as First Crop and Ringwood peas, and Mazagan and Long-pod beans. In the fruit garden you may plant currant and gooseberry trees, raspberry canes, strawberries, and hardy fruit-trees of all kinds. In the flower garden you may plant hardy herbaceous plants in any quantity, as you can obtain them and find room for them. As you take the Magazine, we will suggest that a careful perusal of the Calendar of Operations every week will keep you full of work, and if you order the "Garden Oracle" for 1868, you will secure a series of carefully prepared lists of the most beautiful hardy plants, such as will convert any empty garden into a paradise for a trifle, for even a paradise (here) must be paid for. In the "Oracle" too you will have a calendar quite different to that in the Magazine, and so perhaps your work will be double, and in gardening matters the more work the more joy.

Pruning Acacias, Heath, &c.—W. Green.—Plants of this kind are usually pruned after flowering ; in some cases, the growth that follows pruning is pinched back once or twice to increase the bushiness of the plants, care being taken to promote a thorough ripening of the wood to ensure a good bloom again. The bloom never need be lost except in the case of cutting down old plants to stumps, in which case one season's bloom must at least be lost, and the cultivator who cuts them down to stumps may consider himself lucky if he does not lose the plants entirely, especially if they are Cape heaths that he treats this way. Whatever your plants are let them flower first, then prune, and wait till they begin to grow before you replot them.

The Gardener's Magazine.

SATURDAY, NOVEMBER 16, 1867.

THE CHRYSANTHEMUM AS A CONSERVATORY FLOWER is not fully appreciated, though its grandeur is unquestioned, and in its season it has no competitor. With the exception of this noble autumnal flower, there is scarcely anything to be seen in the way of floral beauty at this time of year, for such things as we find in bloom are either past their best or not yet arrived at it. Take the Poinsettia for example, and it may safely be said that we do not need it for another month at least, though it may be supposed to be in perfection from the 1st of November onwards. One good reason, perhaps the sole reason, why the Chrysanthemum is regarded with less favour than it deserves, is that it flowers at a season when the wealthy are least in need of flowers. Certainly in great cities, where it is better cared for than in country places, there are few proprietors of large places at home to enjoy the splendour of the display which many an enthusiastic gardener produces year after year, as if devotion to a forlorn hope had some sort of charm about it. Nevertheless, though in great cities, where the Chrysanthemum is best understood, it finds less favour from the great, and is especially the flower of the humbler classes,—for in one case it is the gardener's especial pet, and in another the only flower the mechanic can hope to grow creditably,—yet at many country seats, where hunting and shooting keep a good company together until late in the year, this splendid subject ought to have much more attention than it obtains; for it is not only capable of affording a substitute for other flowers during six or eight weeks of the gloomiest period of the year, but it offers more variety than any other subject that can be obtained in flower at the same season. Let us just consider what flowers are available for November and December. Out of doors we may say there are none at all except these, and they last as long as weather allows them. Within doors the Poinsettia, the Camellia, the Thyracanthus, and a few heaths, make up the November garland; and if the Chinese primula be added, the catalogue is complete of subjects that contribute in any eminent degree to the production of a display. The Chrysanthemum literally supersedes all these things while it lasts, and we may consider it good for six weeks. As to variety, it is true we want brighter shades of red and crimson, and no one would object to a dash of heavenly blue amongst the colours; but we have superb shades of white, blush, yellow, and rose colour, and the grand outlines of the best specimen blooms afford a pleasure to appreciative eyes altogether distinct from that resulting from a rich display of colours. No one who has seen Chrysanthemums well done can remain indifferent to their beauties and their uses. We have lately seen at Mr. Salter's nursery, Mr. Forsyth's nursery, in the great conservatory at Buckingham Palace, where Mr. Wyness continues to cultivate his favourite flower with a skill and arduous scarcely matched elsewhere; in the garden of Mr. Crute, at Holloway; and in many other places,—collections of these flowers so well grown and so tastefully grouped, that we are compelled to marvel that in so many places where a display at this season would be appropriate the Chrysanthemum meets with but small attention. There is, indeed, in many minds a prejudice against it—perhaps because it has always been a middle-class subject, not costing thousands of pounds to obtain a few plants, or requiring elaborate treatment in its cultivation. That there are defects in the flower itself cannot be denied; perhaps we may find defects in the customary modes of displaying them; perhaps also there may be something wanting to render exhibitions of Chrysanthemums largely attractive and satisfactory; and if these several defects are removed, we may hope to see the Chrysanthemum rise rapidly in the estimation of persons possessed of means and taste.

Let us look to the flower itself. We find in its varieties pure white, delicate shades of blush and pink, and the purest tones of yellow. There is no pure red, no pure crimson, no true purple; a certain dullness of tone and impurity of colour characterizes every flower that is not white or yellow. Nevertheless many of these impure colours are agreeable, and when skilfully harmonized effective; for example, if we see a good

specimen plant of Alfred Salter contrasted by association with one of the good dark kinds, we forget the defect of colour in our admiration of a beautiful object. There is no pink chrysanthemum of so bright a tint as Christine geranium; no red chrysanthemum so brilliant as Bob Ridley dahlia; no crimson chrysanthemum equal in colour to General Jacqueminot rose. If ever comparisons were odious, we suspect these are, and therefore we desist. But we may search far and wide and not find a yellow flower to surpass in purity and depth of colour a fine Jardin des Plantes or Chevalier Damage; and if we are to make comparisons in a large manner, we shall have to take into account the time at which our favourite arrives at perfection, when there are no other flowers with which to compare it, and this consideration compels us to crown it Queen of the Autumn, and to recognize it as reigning alone in fullest splendour when the last rose of summer is faded and gone. Nevertheless, as critics we are bound to lament the absence of certain shades of colour commonly met with amongst flowers in this useful subject; and as we have seen immense improvement effected in the varieties, we will hope that cross-breeding and careful selecting may result at last in the production of the pure tints of red, crimson, and purple, with their intermediates, which are as yet so conspicuous by their absence.

In the grouping of Chrysanthemums for display, the greatest difficulty is to hide their legs. When grown as round-headed dwarf bushes, as Mr. Forsyth manages them so admirably, we should prefer not to hide any portion of the plant; even the pot ceases to be inelegant, the symmetry of the whole from head to foot is so complete. This is the form best adapted certainly for the embellishment of the conservatory, and the one that gentlemen's gardeners should mostly give their minds to. But the tall plants, grown for the supply of a few of the very finest flowers, are scarcely so elegant that they may be obtruded upon the view in their entirety without inspiring unkind criticism. We have enjoyed the magnificent flowers which Mr. Wyness has grown this season at Buckingham Palace much more because the gaunt plants are majestically with masses of foliage, out of which the flowers rise majestically on stems varying from six to twelve feet high. Mr. Salter manages to make them hide each other's legs by packing them close on the back stage; but the beauty of his display is very much enhanced by the free association with the Chrysanthemums of plants that attract attention by the distinctive character of their foliage. We are the more anxious to impress upon our friends the necessity of tasteful display after they have given the flower all their skill, because there is a notion prevalent amongst Chrysanthemum growers, that as good wine needs no bush, so good examples of their favourite need no assistance from other subjects when grouped for the purposes of decoration, which is a mistake.

The prejudice against deriving assistance from other plants has prevented the exhibitions of this flower from attaining the popularity they deserve. On this point we have spoken frequently, and not altogether in vain. The Brixton Hill Chrysanthemum Society first set the example of associating fruits and fine foliage plants with the *pièce de résistance*, and the exhibitions at Brixton Hill have always been the most tasteful, and in general management and effect models for all the other London societies. The first Guildhall exhibition afforded a more comprehensive and satisfactory example of the appropriateness of fruit and foliage as accompaniments to Chrysanthemums, and we have much pleasure in recording that the cultivators of Stoke Newington joined in the broad march of improvement, and admitted foliage plants, so that there was a goodly breadth of green to bring out the colours of the flowers. We would urge upon all who wish to see the Chrysanthemum take the high place it is entitled to in the floral world, to pay attention to its defects as well as to its virtues. If it is worth growing well, it is worth showing well; and if the general public are invited to the shows, they should be made as beautiful and complete as is possible, by the association with the flowers of other subjects adapted to give variety and dignity to the *tout ensemble*.

A YOUTH, appropriately named Franklin, and aged thirteen years, is said by the *Mechanic's Magazine* to have discovered a mode of causing a vacuum without condensation, which will save half the fuel hitherto used in working steam-engines.

THE TRADE ARE CAUTIONED not to part with goods to strangers without first obtaining payment, or some satisfactory proof that the purchasers are not intending purloiners. Several cases have been brought under our notice of late in which swindlers have obtained possession of goods in a manner so easy, that we are tempted to suppose that some members of the nursery trade rather enjoy the process of being fleeced. But as there may be a few of our trade-readers who prefer the safe side, we give the word of caution that an organized system is being industriously and cleverly carried out, and the victims are already numerous.

THERE WILL BE NO EXHIBITION OF FLOWERS IN THE GUILDHALL OF THE CITY OF LONDON THIS YEAR. The committee of the United Horticultural Society applied several weeks since to the Corporation for a grant of the hall, and did not succeed in obtaining it. It appears highly probable that the subscribers to the society will have nothing at all for their subscriptions in 1867. This perhaps will not trouble the committee, but it is scarcely likely that subscriptions will multiply, or that the society will recover in any degree from the almost total wreck it suffered when the president steered it into the midst of the tent-bedsteads and pink calico, and threw all its rights overboard to keep the thing afloat, when it need not have been in danger. If the secretary had been awake and mindful of his duty, intending exhibitors would have been informed of the failure of the appeal to the Corporation in sufficient time to render these remarks unnecessary. But we cannot hear of exhibitors having actually cut their flowers for the show *one full week after it was known the hall would not be granted*, without giving publicity to the fact that the Corporation has not granted the hall, and to our opinion that president and secretary are conspicuously incompetent persons.

It is said that a "vegetable gas" has been invented which gives a brilliant light, has no offensive smell, and can be generated in any ordinary kitchen range.

THE *Scotsman* of the 4th inst. reports, as an instance of the mildness of the weather, that a gentleman residing in the neighbourhood of Edinburgh brought to the office of that journal, on Saturday last, a bouquet of standard roses, the second crop of the season, and a specimen of ripe strawberries, all grown in the open air.

EXHIBITIONS OF CHRYSANTHEMUMS, in addition to those announced last week, will take place at the Royal Victor, Old Ford Road, Victoria Park, on Monday and Tuesday next, November 18th and 19th; and at the Marlborough Arms, South Street, Camberwell, on the 25th, 26th, and 27th.

M. GAY'S HERBARIUM.—A valuable collection of plants is now offered for sale. The collection of the Swiss botanist, the late M. Gay, is to be sold, and is said to be on view at the Jardin des Plantes, Paris. The price is fixed at 30,000 francs. The herbarium embraces the whole European flora. It contains 90,000 specimens, each specimen bearing a description and analysis. These statements are made on the authority of Dr. Henri de Saussure.

AUCTION SALES OF PLANTS have been sufficiently numerous of late to prove discouraging in respect of prices, yet useful goods have realized good prices; and if we are to judge of the state of trade by this particular test, we must own that it affords a cheering prospect. The mere sweepings of nurseries will, of course, never realize their actual values, and if sold under the hammer must go for next to naught. But there are no evidences at all discernible of a scarcity of money or a lack of speculative spirit in the prices obtained at auction sales for serviceable nursery stock of any kind. The sale at Mr. Hollamby's, Tunbridge Wells, by Messrs. Protheroe and Morris, afforded an example of the plentifulness of buyers, and their readiness to bid with spirit—the result in part, no doubt, of the extensive building operations in progress in the district. As Mr. M'Nab has been lately advocating the pruning of the Cedrus deodora, we were interested in the sale of a batch of these trees that had been systematically pruned, and which readily brought far larger prices than trees of the same size that had never had the benefit of such treatment. These pruned deodars were most elegant in outlines and proportions, richly furnished, and of a brighter tone of colour than the unpruned trees. At the sale, by the same firm, at Mr. Jackson's, Kingston, there was a large attendance, and the prices obtained were far higher than could be expected were trade in a depressed condition. Whatever, therefore, may be said in other departments of industry in respect of the badness of the times, recent nursery sales afford abundant reason for confidence and cheerfulness. While on this subject we direct attention to the sale announced for Monday next and following days, at the Goldworth Nurseries, Woking, in consequence of the death of Mr. Robert Donald. This will comprise some large lots of useful trees, and several extensive special collections of great value. For the particulars we refer to our advertising columns, but the importance of the event demands this brief preliminary notice of it.

MR. JAMES CUTHILL, so well known as a successful cultivator of strawberries, cucumbers, mushrooms, &c., for the London markets, died at his residence at Denmark Hill, Camberwell, on the 5th instant, in the 62nd year of his age. Mr. Cuthill contributed most valuable material to the literature of horticulture; he was the author of a celebrated series of papers on "Market-Gardening round London," and of some treatises on the cultivation of the cucumber, mushroom, &c. He occasionally communicated with the horticultural periodicals, and the pages of the *Gardener's Magazine* have been frequently enriched by the aid of his pen. To say that it is with regret we record his demise, is to use a familiar phrase with much more meaning than it is the wont to assign to it.

ESPARTO GRASS.—*Atocha*, or Spanish grass, better known in England as esparto, and to botanists as *Stipa spicata*, has been lately brought into notice by *The Stationer* as adapted for manufacturing purposes. This grass when gathered or plucked from the parent root, merely needs drying in the sun to become available, after certain preparations, for many useful purposes, for which it is particularly adaptable from its strong fibrous texture. It is a spontaneous, natural, and uncultivated product, but is confined to certain soils and localities, beyond which it is rarely found.

In its native localities it has hitherto been so abundant that after amply supplying the wants of the neighbouring population, as regards ropes, baskets, and matting, it has furnished a ready and highly combustible fuel for the cottage fire and the baker's oven, and has even been used in the smelting furnaces through the mineral districts of the south of Spain, the privileged region of its luxuriant growth.

Since the discovery of the important use of esparto, which is by no means confined to paper-making, but now extends to articles of apparel and other uses, the material is eagerly sought for in all the southern provinces of Spain and Algeria, especially those on the seaboard, as its carriage

is very expensive in a country so sadly deficient in roads. At first, indeed, the esparto growing near the coast was alone shipped, but as the price advanced, and the demand increased, districts thirty or forty miles in the interior were ransacked, though at a very heavy cost for carriage. The provinces from which the greatest quantity of this plant is shipped are those of Almeria and Murcia, both of which are congenial to its growth, and where it is found in abundance. It is, however, found in all the southern provinces of Spain, and is also plentiful in some parts of the opposite coasts of Africa, from whence it has been shipped to England from the port of Oran by Mr. Edward Lloyd, who has established depôts there, and also at Arzew, both French ports on the African coast. The esparto is trussed at these depôts, as we pack hay, by hydraulic pressure, and the bulk is thereby greatly reduced. It is calculated on good authority that about 200,000 tons of atocha have been imported into England within the last five years.

The general price of the material delivered on board may be taken at £3 per ton. But the business is far too profitable to be carried on legitimately, as much coarse or inferior grass is now being shipped, and of an undue weight, in consequence of the grass not being properly dried before being packed. The loss of weight caused by this is a serious drawback to the purchasers; but as esparto must be had, all these circumstances seem to be tolerated in the trade. As the grass grows on waste lands—sometimes the property of individuals, at others of the municipality of the neighbouring towns or villages—the crop of each year is bought by merchants or speculators, who employ the peasants to collect the crop and convey it, after being dried, to the nearest port for shipment. The commission of 5 per cent., allowed by purchasers in England, yields a large profit to all who embark with common prudence in the business, which is carried on with great eagerness and competition. Fortunes have been realised by individuals who were proprietors of these waste lands, consequent on the enormous rise in the value of their property, and much has also been made by speculators who at a proper time purchased the lands at very insignificant prices.

Considering the suddenness with which esparto came into use, the extraordinary demand which prevails for the article, and the other manufacturing purposes for which it is found capable, it is fair to suppose that it will in a few years take its place with cotton, hemp, and wool, as one of the staple and essential bases of manufacturing industry. This is the more extraordinary when it is considered that esparto is merely a weed of natural growth, which requires neither care nor cultivation, and grows on very poor soil.

BEDDING GERANIUMS.—No. XLV.

I read in Horatius (Lib. i. Ep. 18, l. 82)—

*Duleis inexpertis cultura potentis amici;
Expertus metuit. Tu, dum tua navis in alto est,
Hoc age, ne mutata retrorsum te ferat aura,—*

which in plain English means "Don't go to work haphazard in the breeding of geraniums." If the wind blow from the east and you are destined for the west, trim your sails and go on; if you wait till to-morrow, the wind may blow the other way. And if you don't know how to trim the sail, learn by any and every means, and be not ashamed to ask, if the knowledge can be got no other way. At line 92 he says—

*Inter cuncta leges, et per contabere doctos,
Quâ ratione queas traducere lenitor ævum:
Ne te semper inops agitet vœxque cupido,
Ne pavor, et verum medioeriter utillum spes;
Virtutem doctrina parat, Natura ne donet,
Quid minuat curas: quid te tibi reddat amicum,
Quid pure tranquillet; honos an dulce iucllum,
An secretum iter, et fallentis semita vite,—*

which may be literally translated, "If you know not how to proceed in the breeding of geraniums, consult the GARDENER'S MAGAZINE, and there you may find also the elixir of life, the secret of happiness, and the talisman of fortune." There are people who wonder I should read such a heathen as Horace; but how can I help it when he goes so directly into our subject, and with an inspiration worthy of the noble cause? But, with these advices and apothegms to guide us, let us look at a few of the questions that have agitated our minds this long time past; and first as to the treatment of the plant as an annual, which you will remember an uninformed and benighted scribe, supposed by some half-dozen deluded followers to know something, had the temerity to pronounce moonshine. I have told you how to flower them in 100 days certain from the seed; how to do it in 150 days without any difficulty or special care; and this year's work at Stoke Newington must make an end of the argument, and after this I shall say no more about it. On the 18th of March a few seeds were sown in a common seed-pan, and the pan was put on a shelf in the Paxtonian. It never had the help of artificial heat or any special care; it was treated, in fact, just as any one would treat a pan of asters or stocks, with the help only of a common frame. I shall not detain you to say how the plants were dealt with; I know that several weeks elapsed ere one appeared; but let it suffice that they are now a very stoecky stubby lot, housed away safely for the winter, and a considerable proportion of them are blooming freely. The first flowers appeared in the batch on the 15th of August, which affords a new datum towards the general history. In a cold season, with no aid from fire-heat, by means of glass alone (and of course sunshine), seedling geraniums may be flowered in a period of 151 days from the date of sowing the seed. Of course the way of doing it has some relation with the result. The 18th of March may be

called "the nick of time," because then the sun-heat is fast increasing, and there is a long season for growth after the seed has started; to sow later would shorten the growing season, to sow earlier (unless with the aid of heat) would be to lengthen the time, and perhaps ensure the loss of seed or plants by cold, damp, and the other ills that tender vegetation is heir to. Our vegetable pot might, under such treatment as the batch of 1867 were subjected to, become an illustration of the 10th ode of Horace's third book, and in the interests (purely) of vegetable physiology we are bound to quote the first dozen lines—

*Extremum Tanaim si biberes, Lyce,
Sicvo mepta vivo, me tamen aspera
Porrectum ante fores objicere incolis
Ploarces Aquilonibus.
Audis quo strepitu janua, quo nemus
Inter pulchra satum tecta remugiat
Ventis, et positas ut glaciæ nives
Puro minime Jupiter ?
Ingratum Veneri pone superbiam;
Ne currente retro fœuis eat rotâ
Non te Penelopen difficilem prociis
Tyrrhenus genuit parens.*

Now we have to deal with a long string of practical questions, such especially as the influence of pollen and the right way of selecting seed parents. The tricolors absorb so much attention, that one would suppose the great problem of enlarging the top petals, on which we have laboured so steadily at Stoke Newington, had but a slender hold upon the minds of cultivators. But the fancy for leaves will decline in time, and the flowers will again have the attention they deserve. I took particular notice, in a series of carefully-conducted experiments, and I found that, as a rule, no matter what were the parents chosen, the short stamens tended to narrow petals and dwarf plants, and the long stamens to broad petals and robust plants. It is to the influence of long stamens that we are indebted for all such as *Dr. Lindley, Andrew Marvel, Leonidas, Beauty of Suresne, M. Galland*, and other of the grandest of the exhibition varieties, all of which are more or less robust in character, and less inclined to branch about and behave as bedding plants, than those with narrow petals. It is easier to speculate on what may be done than it is to carry one's speculations into effect. As the French say, "*L'imagination galope, le jugement ne va que le pas.*" Nevertheless speculation is the first step towards success in cross-breeding, and the best speculation is that which is based on the largest knowledge of facts. One of the best guiding principles in selecting parents is derived from the fact that a vigorous blood, no matter of what sort, will influence several generations through one contact, as we may observe in the pervading characters of what is called "a strain," where perhaps the originator of the strain has started with only one distinct and powerful-habited plant, possessing suitable qualities, and the characters of that have pervaded more or less a large series of generations. A strain of broad-petalled varieties may thus be obtained by breeding in the first instance from one or two of the best of the broad-petalled kinds, and after the first start the original parents may be thrown away, and pollen may be taken from quite inferior kinds for the sake of colour, yet the seedlings will show the influence of the broad-petalled progenitor from which they have descended, and the characters of ancestry will reappear after several generations which have not displayed a single trace of them. Just as Mr. Tegetmeyer discourses eloquently and ably of "atavism" in the poultry yard, so we may talk with equal seriousness, if with weaker eloquence, upon the persistency of a taint of peculiar blood in the generations of plants, the peculiarities of colour and form appearing again and again in varieties that are many removes from the parents that are more or less reproduced in them. It is owing to this persistency of blood characteristics that particular breeders come to have peculiar strains. A certain style of flower or leaf has taken their fancy, they have bred from it, and, once in the possession of a race thereby, they find that many diverse styles may be introduced into the family, and yet certain of its original characteristics will remain, though varied by the various introductions. Colour is certainly more persistent as a transmitted quality than form. Hence it is that our correspondent W. (page 464, October 26th) finds that seedlings resulting from a determinate cross produce flowers which for the most part resemble one of the parents, rather than presenting a compound of their respective tints. I should expect always from seedlings derived from Christine in any way, whether as a father or a mother, about nine-tenths of pink flowers, no matter what the other parent, so powerful is this variety as a parent to transmit its colour to its progeny. Yet colours are blended by crossing; were it otherwise there would be but little interest in the proceeding. We

can prove the origin of several of our rich red and crimson varieties to be the actual admixture of the colours of the two parents; just as mulattos or sallow yellowish-complexioned individuals of the human race are commonly and correctly accounted the results of mingled white and black blood. The proportion of the respective progenital elements in crooles can be tolerably well predicated by experienced ethnologists, but there is always a liability to error in such attempted predications, by the occasional reappearance of the character of an ancestor after several generations free from any intermingling of such blood. Dr. Denny can point to several decided examples of the intermingling of the colours of the flowers, the registry of parentage being about as infallible as any genealogy can be. There is in Dr. Denny's lot at this moment a superb truss of flowers on a plant the parents of which are Mrs. Pollock and Rose Rondatler, the colour of the flowers being exactly intermediate between the two. It might almost be said, that unless the colours could be combined there would be no advantage and no pleasure in cross-breeding for flowers. But they can be combined with at least quite as much certainty as the colours of the leaves. I crossed a lot of whites with pollen from pink and scarlet varieties, and got a whole batch of painted flowers amounting to about half the group, the remainder being white, pink, or red selfs of various shades. In some of the purest whites of this lot, the effect of the cross could be sometimes seen in a tinge of colour at the edges of the petals or round the eye, forming a ring; and these indications were usually brought out by strong sunshine or cold, suggesting that the colours of both parents were there, but in ordinary circumstances one of the two colours was latent. Here is a sort of justification in the laws of the vegetable kingdom of that famous law maxim, on which our legalized system of inheritance is founded, *Jus sanguinis, quod in legitimis, successioneibus spectatur, ipso nativitate tempore quasitum est.* It follows that the breeder can shape his plans for the purpose he has in view, and is not a sport for the winds of chance, and ought therefore never to talk of a chance sport in connexion with the results of his operations. Indeed, it is quite a question if the term "sport," as we understand and use it, has any instructive use at all; for what seems to be the child of chance is always doubtless the expression of congenital causes, and the so-called sport is but the proof of some peculiarity of ancestors.

In the breeding for leaves, it appears to be a rule that green cotyledons are evidence of the incapacity of the plant to produce variegated leaves; and on the other hand, if the cotyledons are variegated, we may confidently expect variegated shoots some time or other, even though the plant may grow beyond the cotyledons without a particle of variegation for months, and even for years. If the cotyledons are whitish, the subsequent variegation will be more diffuse and profuse than if the variegation be yellow, and occasionally plants that began life with white or whitish cotyledons will, after producing abundance of healthy green leaves, become wholly white, and then perish. In emerging from the seed, the plant gives some indications of what complexion it will have hereafter, though we have not got so far in our knowledge as to be able to predicate whether the future variegation will be good or bad. For the present, we may learn as much, and doubtless as usefully from failures as from successes, and in breeding geraniums fulfil for ourselves the truth of the old French saw, *La bonne fortune et la mauvaise sont nécessaires à l'homme, pour le rendre habile*,—which means that if you give a cabman a sovereign instead of a shilling, you will learn to look at your money next time, and a small mistake may save you from making a large one.

The rules generally accepted by the old florists appear to be not in the least disturbed by recent experiments and inquiries; but, as they did not breed for leaves, our new experiences properly open another chapter in addition to all they knew and taught. It is abundantly evident, as of old, that *form* is most directly conveyed through the maternal parentage, and *colour* through the paternal. In breeding for leaves, the first necessity is a seed parent with leaves of a fine outline and texture, whether zoned or green is another matter, and must depend upon the kind of leaf required in the offspring. But a round, stout, flat, refined leaf is the first necessity, and if tricolors are desired, it is well to select a seed parent with a bold dark zone. For the pollen parent a brightly-coloured leaf of some sort is desirable: if good in form all the better, but colour is the grand requisite. As for the rest, it is all matter of observation. Many of our most esteemed varieties are bad parents; some that are of little value are good parents. Thus the breeder is encouraged to observe and reflect, and, acting on certain ascertained and definite data, he may vary his operations, and gain knowledge of minute details to superadd to the wisdom that is already written down. Let us ever bear in mind that the attribution of anything to chance is a virtual closing of the eyes to truth, and while our eyes are open we must search for

laws and principles, and consider accidents and chances as the expressions of laws unexplained. *Substantia prior et dignior est accidente.*

S. H.

NOTES ON BEDDERS.

It has occurred to me that a few words from an amateur who has seen nearly all, and grown a large number, of the "sensation" and other bedders which have been introduced or brought into notice during the last few years, and has consequently "bought" his experience, and that rather dearly, may be of service to other amateurs who are now arranging their plans for next year's display, and who may not have had opportunities of visiting the gardens and nurseries, and so judging for themselves. I will confine my remarks in this paper chiefly to those plants which I know to be good, and recommend your readers to give a trial.

Arabis alpina variegata, or "Golden Arabis."—An exceedingly pretty, free-growing, variegated, dwarf plant, suitable for edging, forming angles, stripes, or squares in mosaic work, or growing on a rockery. It is easily propagated by division either in the autumn or spring, and is quite hardy. It forms a compact and most beautiful edging, next to grass, and in the early part of the year its pretty white blooms render it extremely interesting. It has been very much admired during the past season by all who have seen it. I cannot too strongly recommend it.

Arabis lucida variegata.—This too is remarkably beautiful, and in habit very similar to the foregoing, and where it can be grown is not easily surpassed; but I have as yet failed to get it to do well in my garden: the only place I have seen it to perfection was at Kew, in the summer of '66. It is rather difficult to propagate, at least I have so found it, but it is worthy of a trial.

Amaranthus melancholicus ruber.—This, as usual, has been grand during the whole of the summer, and is, after all, far better and safer than *Achyranthus Verschaffeltii* or *Coleus Verschaffeltii*. It should be carefully grown in spring, and not planted out before the first week in June: with me it has grown in strength as robust as a cabbage, and the colouring of the foliage (dark shaded carmine) has up to the beginning of October been superb.

Achyranthus Verschaffeltii.—This is the third year it has been grown by me, and, so that it may have a fair trial, it has been planted in various situations. For those who require their parterre to look gay in August and September, it is certainly a very useful and pretty plant; but I have finally discarded it, for the simple reason that during June and July and the early part of August it has every year been wretchedly poor in every respect. At the end of the season it is unquestionably fine—even now (2nd Nov.) it is better than it has been the whole of the season, and has not suffered in the least from the slight frosts we have had.

Ageratum Prince Alfred.—A dwarf variety with rather pale blue flowers: it is exceedingly pretty, and suitable for small beds. It has bloomed very freely, and is an acquisition.

Calceolaria aurea floribunda.—I have introduced this to enable me to say a word in its favour, in contravention to what has been urged by so many correspondents. During this and previous years, with me, it has been a mass of bloom for many months, and even now is looking well—owing, I believe, to my having adopted the plan recommended by my friend the conductor of this Magazine, viz.—to deeply trench and well manure the bed before planting; this I did, and the plants, which were by no means in robust health, were pegged down two or three times during the early part of the season. This caused the side shoots to throw well up and bloom most abundantly. Last year my calceolarias grew very freely (Mr. Hibberd told me they were the best he had seen), but oddly enough they ceased blooming early in the season. I strike mine in a "cold frame," and early in the spring pot them off, so that by the time they are required for bedding out they turn out with good balls. I consider it most essential not to permit the soil to get dry in the early part of the year. Dryness at the root I believe to be the cause of the disease so much complained of.

Polemonium caruleum variegatum.—This is extremely pretty, and will doubtless be grand in a ribbon border. My stock is as yet small, but I am so much pleased with its appearance that I intend to huddle it out somewhat largely in '68, and hope to be able next autumn to give you the result of my experience.

Tagesia signata pumila.—When true, a most beautiful dwarf and free-flowering bedder. The bloom is bright yellow, and the foliage very neat and pretty. It has bloomed very freely with me the whole of the season, and is now full of flower. To those who fail in growing calceolarias I strongly recommend a trial of it, feeling sure they cannot fail to be pleased with the result. There are two distinct forms of this in cultivation: one grows two feet high, flowers sparingly, and looks weedy; the other grows one foot (or less) high, blooms profusely, and makes a brilliant effect.

Viola cornuta.—To those who have not yet grown this much lauded plant, and who contemplate purchasing it, I would simply give the advice offered by *Punch*, "to those about to marry," viz., "Don't." My stock was purchased from Messrs. E. G. Henderson and Co., and is, I believe, the same variety as grown by Mr. Wills. With me it grew freely and bloomed magnificently up to the end of July. The weather then became warm and dry, and, to my great disappointment and disgust (because it entirely spoiled the effect of my beds), "it went off." The blooms curled and the plants altogether looked as miserable as they well could do, dying in patches. When the wet weather set in, as it did for a week or two at the beginning of August, it somewhat recovered, but eventually resumed its wretched appearance and became a "total wreck." In another part of the garden, where it formed an edging to a bed of calceolaria, it failed in a precisely similar manner. I should add, the beds were deeply trenched and well dressed in the spring, and in one case the situation was most suitable, the bed being partially shaded. I have now purchased a stock of "Lutea," and you shall hear the result in "due course." "Cornuta" will no doubt do well in a damp and shaded situation, but even there the blooms are too "flimsy," and the colour not sufficiently strong to make an effective bed.

Dactylis glomerata variegata.—"The gem of the season,"—at least it is my first season of growing it. It is a most beautiful dwarf variegated grass, hardy, and easily propagated by division. I shall not readily forget the first night I had it at Messrs. Henderson's, Wellington Road Nurseries; it literally charmed me, and my first question was, "How much for the lot?" The reply, however, cooled my ardour, but it did not prevent my carrying off sufficient to plant several beds; and the result has fully borne out the description so frequently given of it by our able conductor. I know of nothing so really beautiful and graceful for bedding purposes; a line in a ribbon border would be magnificent, and could not fail to meet the approval even

of the most fastidious of amateurs. Thanks to a good friend, I have recently received about two dozen "clumps" of it, which has been torn asunder, and I now boast of a stock of nearly three thousand plants, in thumb pots, with which I mean to make lines of light next season. I cannot too strongly recommend my amateur readers to get a stock and give it a trial; but a word of caution is here necessary—there are two varieties of *Dactylis glomerata variegata*. I happened in the first place to purchase of a local nurseryman the spurious one, which is in every respect as bad and worthless as the true variety is good and valuable. I observe Messrs. Henderson advertise two varieties of this grass—one under the same title as the heading of this paragraph, and the other as "Elegantissima;" the latter is what I possess. Are there three varieties? The foliage of the plants recently sent to me is not so white as "Elegantissima" but this I attribute to its having been grown in heavier soil than mine, and probably in the shade. Neither of the two I have is like that which I first purchased in the neighbourhood.

Variegated Geranium Flower of Spring.—This is indeed a gem. The foliage is good in form, and the bloom of an exceedingly pleasing bright cerise colour. This and Daybreak I consider far superior to any other variety. Silver Chain is well spoken of, and is certainly good, but I have not yet given it a fair trial.

Geranium Variegated Nosegay.—When in bloom this is very pretty and distinct. A line of it here in a ribbon border has been very much admired this season. I do not like either Queen of Queens or Stella Variegata; in my opinion, the preceding are very far superior in every respect.

Geranium Cloth-of-Gold.—This has not done well with me. I have tried both old and young plants, but the result is by no means satisfactory. I think it will eventually have to be discarded for Golden Chain, which is certainly the better variety of the two, and grows much more freely.

Echeveria secunda glauca.—One of Mr. Gibson's (Battersea Park) pots, and truly beautiful it is, either as an edging for beds in summer or for decoration of the conservatory in the winter. I first saw it in the sub-tropical garden at Battersea, and have at length succeeded in getting a fine stock of it. It is a most charming plant, and for gardens where bedding out is "cherished" it will be found to be most valuable.

Chrysanthemum (variegated) Sensation.—This is one of the few really good bedders recently sent out. It has done remarkably well here as an edging, kept pegged down and pinched to regulate the height. I can only say to those to whom it is as yet unknown, Purchase at once, propagate it, and tell me next autumn what you think of my recommendation.

Pyrethrum Golden Feather.—This has retained its colour well with me during the summer, and has the advantage of being easily propagated and kept through the winter. My stock is, however, small, and I am unable to speak positively as to its value as a bedder; but if it does as well next summer as it has this, I shall certainly retain it as "one of the good things" not to be lost. It is useful as a substitute for Cloth-of-Gold or Golden Chain Geraniums where these do not flourish, and is moreover cheaper than geraniums, and easier kept and increased.

I would add, in closing these remarks, that my garden is "hot and dry," and soil light; notwithstanding my plants, with scarcely an exception, have done remarkably well, have grown and bloomed freely, equal in every respect to the best gardens I have seen this year in various parts of the country; and it may surprise your readers when I tell them that *not a plant has been watered the whole season*. I believe that many failures result from the use of the water-pot; it causes the plants to root on the surface instead of deep in the soil, so that they must either be constantly watered in dry weather almost daily, or they fail altogether. I have tried both systems, and my plan now is to depend on nature for moisture.

Should you consider my remarks of any service (it is my first attempt), I shall be happy occasionally to give the result of my experience both in the cultivation of bedders and other plants.

The Laurels, Taunton.

J. B. SAUNDERS.

P.S. On the night of Saturday, the 2nd inst., we had our first severe frost, which has entirely destroyed the scarlet-runners and dahlias, the latter of which were in fine bloom up to that time.

MR. A. FORSYTH'S EXHIBITION OF CHRYSANTHEMUMS.

The Brunswick Nursery, Stoke Newington, has been for some time past extremely gay with specimen chrysanthemums, in the cultivation of which Mr. A. Forsyth stands first of all the men of England, and has no doubt taken more prizes for these things than any other person living. Every man has a forte, said Artemus Ward, and it's not every man's forte to take the census. But it is Mr. Forsyth's forte to grow chrysanthemums, and any of our readers who are unfamiliar with the nature of the display which a large collection of well-grown plants is capable of producing, are advised to find their way to Mr. Forsyth's at once, and see the exhibition while it is still fresh and beautiful. The principal display is in the neat small show-house adjoining the high road, and it is better perhaps that the house is small, for the splendour of the effect may induce many private cultivators to do justice to this noble flower, who might consider it beyond their means and skill, were the demonstration made in a great and costly structure, and accompanied with elaborate accessories. This exhibition is in fact exactly what thousands of ladies and gentlemen of moderate means might have for their own private enjoyment. The requisites are not costly plants, or costly plant houses, but a little skill, care, and patience in the production of the specimens, and a bit of shelter for their flowering. A plant costing sixpence or a shilling may be grown to enormous dimensions and become a mountain of gorgeous flowers within a year, and then only requires to be kept a few weeks under glass to complete its flowering, and gratify its owner with a feast of beauty. The show-house has a large central stage, on which are placed a number of the rougher specimens, rather closely crowded, each showing some half-dozen splendid flowers. There are low stages all round filled with superbly-grown convex specimens, in perfect training and in gorgeous richness of bloom. In the other houses we find plenty of bush, pyramid, and standard poupones. As usual, the Codo Nulli series justify their collective designation; they are exceedingly rich in flowers, and extremely neat and beautifully finished. Bob is good, but late; La Vogue and White Trevemum are favourites for the abundance of their flowers, and their admirable adaptability to form neat dense bushes and compact-headed standards.

The large-flowering incurved varieties will always claim and obtain attention. Our first inquiry here is in respect of novelties, and we succeed in discovering a few. We must dispose of these at once, and gladly direct the attention of our readers to them.

Dr. Sharp (Forsyth), a fine relaxed flower of the largest size, rather

flat, but otherwise symmetrical, and nicely finished; colour pure crimson, the growth short-jointed and leafy. A valuable addition to the dark-coloured varieties, and rather early to flower.

Mrs. Sharp (Forsyth), a fine incurved show flower of large size and perfect finish, the petals (florets) broad, stout, and smooth, the colour rich pinkish rose, with bright silvery turnover; a highly-finished and attractive flower.

Mrs. George Rundell (Forsyth), a fine incurved flower of the most perfect form and stout lasting substance; colour pure white, changing with age to a beautiful rosy lilac on the outside petals, and hence up to a certain point improving with age; when young and fresh, this is quite an advance on *Vesta*, when aged it is equal to any of the shaded whites.

In the general collection there are fine examples of *Formosum*, *Prince of Wales*, a useful dark variety; *General Hardinge*, *Lucidum*, *Little Harry*, one of the very best in existence; *Julia Lagravere*, a grand dark flower, rather late; *Gloria Mundi*, a good incurved yellow; *Jardin des Plantes*, the best incurved yellow hitherto; *Yellow Beverley*, very fine in form and finish; *John Salter*, a grand show flower, worthy of its name; *Sir Stafford Carey*, a curious but useful flower; *Rev. Joshua Dix*, a splendid orange-red flower; *Lady Tulford*, rich rosy lilac with silvery turnover; *Duchess of Buckingham*, pure white, finely incurved; *Prince Alfred*, a grand variety of a rich rosy crimson colour, and unsurpassed, when well grown, for exhibition purposes; *Princess of Wales*, pearly white with a soft tinge of rosy lilac which deepens with age, most superb and unequalled in its colour.

The collection of pompones is extensive, and the plants are admirably grown. The visitor will be sure to be attracted by the superior beauties of such varieties as *Aigle d'Or*, a splendid yellow; *General Canrobert*, yellow; *Canary Bird*, bright yellow; *Durand*, rosy carmine; *Florence*, dark cherry red, fine; *La Vogue*, bright gold; *Justine Tessier*, sulphur white; *Madame E. Donage*, a fine white—one of the best for decorative purposes, as it opens all its buds well; *Miss Turner*, pure white, first-rate; *Mrs. Dix*, bluish shading to rose, first-rate; *White Trevenna*, very fine, but rarely making more than one good flower on a stem, therefore requiring careful management, and not well adapted for off-hand cultivation; *Rose Trevenna*, very lively and pretty; *Ingram's Little Gem*, a lovely peach-blush flower of perfect form and lasting long in flower. We might extend these enumerations, but we noted only the most distinct varieties, and here make an end. The plant houses at this nursery are economical, elegant, and admirably adapted for the several purposes for which they were constructed; we advise our practical readers to take note of them.

S. II.

PROTECTION OF BRITISH BIRDS.

The following Petition will be presented to Parliament by the Rev. F. O. Morris early in the approaching session:—

"The Petition of the undersigned Rector of Nunburnholme in the County of York, sheweth,

That birds perform a most useful part in the economy of nature.

That if they are unduly destroyed, insects increase in similar proportion, and do vast damage to the produce of both farms and gardens.

That birds are ornamental as well as useful, and give great pleasure and instruction to naturalists and others who observe their habits.

That owing to the indiscriminate and untaxed use of guns they are recklessly destroyed in great numbers every year.

That many important and useful species have in this way already become extinct in Britain, and that others have become more or less rare, and will in like manner be exterminated if some means for their protection and preservation is not adopted.

That in the year 1864 your petitioner published a suggestion that there should be a tax laid on guns for this object.

That such tax would bring in a very large revenue to the Exchequer.

That this recommendation has lately been again made in the *Times* newspaper by a high official of the Tax department.

That its enactment would at the same time do away with a vast amount of poaching.

That it would be the means of saving many lives, which at present are sacrificed every year by the incautious use of firearms in every one's hands *ad libitum*, as well as otherwise.

That the French Senate has already passed strict laws for the protection of their native birds, it having been found that their destruction had had its natural result in the most serious ravages of insects on crops of various kinds.

That most stringent laws of a similar kind are in force in America at the present moment, and have been for some years.

That the 'Report of the Commissioners for Agriculture for 1864,' printed at the General Printing Office, Washington, 1865, shows that not only pheasants, partridges, grouse, quail, snipe, woodcock, teal, plover, wood duck, gray duck, black duck, wild geese, and wild turkey, as well as also trout, hares, rabbits, also thrushes, larks, linnets, curlews, and many other birds down to robins and wrens, are protected by game licenses, and that heavy fines are incurred for 'killing, taking, or having in possession at any season of the year' any of the above-named. That owners of land can forbid any shooting over their grounds, even during the time of the year when game of any kind is in season.

That a fine is imposed of twenty dollars for killing grouse or heath hen at any time of the year, with ten dollars to the owner of the grounds, and a search warrant authorized against any one suspected of the offence, as is the case in Massachusetts, and a fine of a dollar imposed for each sparrow killed or each sparrow's nest robbed. That in Rhode Island there are fines for buying or selling, as well as for killing or destroying certain birds, with additional fines to the owner of the land, besides liberty to sue for damages for trespass.

That in Delaware the laws are strict, and the penalties in some cases amount to 200 dollars.

That in the State of New York snaring quail is forbidden at any time.

That in Pennsylvania and other States strict laws are enacted, and in Ohio the selling or having in possession incurs the same penalties as killing or taking certain specified birds or animals.

That in like manner in Australia severe laws have been enacted for the protection of birds.

That your petitioner hopes that in the wisdom of Parliament these examples will be followed, and a heavy tax imposed on the possession of a gun, pistols being amply sufficient for all purposes of protection, and that the law of trespass be made more stringent with the like object in view, the protection, within due bounds, of each and all of our native birds.

And your petitioner, &c."

EXPERIMENTAL CULTURE OF ZONAL PELARGONIUMS.

I can only find time to reply very briefly to your correspondent's query to the meaning of the expression "breaking into." Your remark, I believe, referred solely to plants having several leaves hitherto nearly or entirely green, but where the later leaves were showing splashes of colour, and not to plants in the seed-leaf stage. The result of my experiment bears out your correspondent's experience—viz., that where the cotyledons were entirely green the plants exhibit no signs of variegation. It seems also certain that where even the slightest mark or splash existed on either cotyledon, sooner or later the plant exhibits variegation; for if the plant grows up with foliage entirely green, when the eye which was at the foot-stalk of the cotyledon breaks it will be variegated on one side if one cotyledon only showed variegation. I notice that where one cotyledon was entirely green, and one considerably variegated, the plant grew up with variegated leaves and leaflets on one side of the plant, and green on the other. The plant afterwards divided—that is, branched into two main stems—on the one side (viz., the one of the variegated cotyledon) the branch became completely variegated, the other entirely green.

I observe, too, that the cotyledons of plants which assume the silver type show very considerably more variegation than the golden. The fact of the eye at the foot-stalk of the splashed cotyledon of an entirely green plant assuming the variegation when it pushes into a shoot, suggested the forcing into growth the eye from the foot-stalk of the leaf of a breaking plant which possessed more beauty or regularity of marking than its fellows; and I am of opinion, from the few trials I have made, that by this means you may obtain a shoot resembling the leaf in question.

Are the shoots thus obtained, as well as those which come from the foot-stalk of the cotyledon differing from the main foliage of the plant, to be considered in seedlings as sports? Because it seems that the strongest and most beautiful varieties of the tricolors are thus obtained, most of the plants whose entire foliage is variegated from the first being deficient in vigour of constitution.

My seedlings have not flowered sufficiently for me to express a decided opinion of the results of parentage, but, as far as I can judge up to the present, my experience does not bear out your correspondent's; for there seems to me to be a blending of the colours of the parents in the offspring: for instance, offspring of *Mrs. Pollock* and *Madame Vaucher*, a deep pink; *Rose Rendatler* and *Mrs. Pollock*, a bright cerise.

The watching for the result of various crosses, and the different phases a number of seedlings pass through, carries with it an interest amounting almost to excitement; and I believe, beyond the amusement it affords, much may be gleaned as a guidance in our attempts to obtain a given result. Much, doubtless, could be gained by comparing notes; and if professional florists, jealous of their superior knowledge, are not disposed to publish their experiments, it is in the power of amateurs to assist one another by so doing: for instance, if by a number of comparisons we could ascertain for certain that green cotyledons never produced any variegation. Where space is an object, one whose sole object was to obtain tricolors could at the onset put aside a large proportion of his seedlings, provided he knew that green cotyledons were destitute of promise.

JOHN DENNY, M.D.

SEEDLING GRAPES.

Having for the last ten years been trying experiments in the crossing and rearing grapes from seed, I have had some singular productions, many indifferently, some encouraging, and others highly successful; but some which I have fruited for the first time this season have exhibited what I consider a singular phenomenon in the colouring of their fruit. Thinking it might be interesting to your readers who may not have tried similar experiments, I have penned these few remarks. My chief object being to get some new and improved varieties, combining as many good properties as possible, I selected for breeding from—*Snow's Black Muscat* *Hamburgh*, as being one of our most esteemed grapes for flavour, &c.; *Lady Downes*, which is not surpassed for blackness of colour and long keeping; and the *Champion Muscat*, originally raised by me, the parents of which were the *Champion Hamburgh* and the *large Canon Hall Muscat*. This, which is now being sent out, is a very superior grape for flavour, size of berry, strength of foot-stalks, &c., &c.; and if any fault whatever can be assigned to it, it is want of colour, as it does not come a jet black, it being only red, or what is called foxy or grizzly coloured. This grape having so many first-rate qualities, but lacking a deep black, I crossed with the *Snow's Black Muscat Hamburgh*, with the view to perfect it in colour; but, singular to say, in the produce from this operation I have got an identical *Champion Muscat* in shape as well as size of berry, and every other property, only the colour is a deep yellow, and it ripens ten days or a fortnight earlier than the common *Black Hamburgh*, when grown in the same house. I fancy it will be a rival to the *Muscat of Alexandria*. A year or two ago, Mr. Thomson, of Dalkeith, raised a white or golden-coloured *Hamburgh* from seed of the common *Hamburgh*, and, if I remember, it was without crossing. I could scarcely credit this at first, but now I can thoroughly corroborate it from practical experience; for I have got from *Snow's Black Muscat Hamburgh* an identical white and a yellowish shaded one, exactly the same in flavour and shape; and again, from the *Black Lady Downes*, crossed with a *White Muscat*, I have got a yellowish green grape, in appearance the same as the *Muscat of Alexandria*, only a little more like a rifle-ball in shape of berries; the flesh firm, like the *Muscat*, and flavour about the same. That is three light-coloured grapes originated from dark parents. A fourth, a seedling from *Lady Downes* crossed with *Snow's Black Muscat Hamburgh*: the result from this last is a largish or rather oval berry, similar in size to the seed-bearing parent, *Lady Downes*, only a white, or, more strictly speaking, a greenish-yellow shaded grape, with a great portion of the flavour of the male parent. Singular to say, I never before had so many come so decidedly different in colour. No doubt some of these dark kinds have originated from light-coloured varieties, or such a quantity of light-coloured seedlings would not have been produced.—WILLIAM MELVILLE, *Dalmeny Park Gardens*, in "The Farmer."

A QUIET REBUKE.—A little feminine precocity committed an act of disobedience; and her mother, in correcting her, spoke in no gentle tone of voice. The child threw her arms around her mother's neck, and exclaimed, "Dear mamma, pray forgive me! If I had known how peevish it would have made you, I wouldn't have done so."

REPORT ON TRIAL CULTURE OF PEAS AT STOKE NEWINGTON, 1867.

(Continued from page 479).

FAIRBEARD'S NONPAREIL (W. Clark), sown May 2, gathered July 16, period 76 days. A good second-rate wrinkled marrow, with long narrow pods, in which the peas are closely compressed. The usual height of this pea is 4½ feet; it is highly prolific, and is rarely affected with mildew.

Thompson's Green Marrow.

FAIRBEARD'S SURPRISE (W. Clark), sown May 2, gathered July 18, period 78 days. A good prolific second-rate blue pea.

ALLIANCE (W. Clark), sown May 2, gathered July 12, period 72 days. A second-rate wrinkled marrow. Last year the height of this variety was 3½ feet. This year it grew only 2 feet high, and bore abundantly.

CLIMAX (W. Clark), sown May 2, gathered July 12, period 72 days. An inferior blue wrinkled marrow, growing 2½ to 3 feet high. It blooms early, and makes a promise of early pods, but is no earlier in the end than some that flower a week later.

FORTY FOLD (Nutting and Sons), sown May 2, gathered July 20, period 80 days. This is a wrinkled marrow, growing 5 feet high, a middling

Blue Excelsior.

Knight's Dwarf Sugar.

cropper of good quality. It is closely related to Champion of England, but in this trial was not so good as that variety.

CHAMPION OF ENGLAND (Sutton and Sons), sown May 2, gathered July 20, period 80 days. The growth of this variety averages here 6 feet; in some districts it is a foot or so less, but wherever it grows at all it bears abundantly, and is one of the finest varieties in cultivation.

RISEING SUN, sown May 2, gathered July 16, period 76 days. This grew freely, and bore abundantly, and was in many respects far better than it ha

American Wonder.

Excelsior Marrow.

been in any previous trial on the same ground. The seed sown was some left over from last year, when it behaved so badly that we marked it as useless. Second-rate.

WOODFORD'S GREEN MARROW (Carter and Co.), sown May 2, gathered July 20, period 80 days. An inferior blue pea, bearing well, but the peas

Albert Edward.

Burbridge's Eclipse.

are small and flavourless. Its fine dark colour renders it a useful market pea in summer, and it is the best to grow for use as split peas for making green-pea soup, as the ripe peas are of a fine deep bluish green colour.

BATT'S WONDER (Carter and Co.). This is so much like Woodford's Marrow that frequent inspection is necessary to distinguish between them. It differs in producing somewhat larger peas, and is about four days later. It is a scarce variety, and Woodford's Marrow is usually supplied in place of it by seedsmen who do not possess the true variety. The only use for this pea is to make green pea soup in winter, its intense green colour rendering it eminently suitable for that purpose.

LORD RAGLAN (W. Clark), sown May 2, gathered July 29, *period* 89 days. A robust dwarf-growing pea, producing an abundance of large sweet peas of the finest quality.

GENERAL HAVELOCK (Wheeler and Sons), sown May 2, gathered July 18, *period* 78 days. A good dwarf pea, the growth averaging 2½ feet. The peas are large and of excellent flavour; the ripe seed is a pale buff colour and wrinkled.

KNIGHT'S DWARF GREEN, sown May 2, gathered July 28, *period* 88 days. This popular variety is the type of an excellent class, in which may be grouped such as Veitel's Perfection, The Prince, Hair's Mammoth, Lord Raglan, &c. It differs but little in appearance from these, but usually lasts longer, and may in some seasons be gathered fresh and good two or three weeks after most other varieties are quite ripened off.

LYNN'S WRINKLED MARROW (Carter and Co.), sown May 2, gathered August 6, *period* 93 days. This is a valuable pea, deserving of more attention than it obtains. The seed is comparatively small, very uniform in colour, which is a dull drab-buff, in form quite angular and slightly wrinkled,

short hooked nose, of a bluish colour, and very tightly packed with bluish green peas. The spurious sort usually admixed with it produces short grass-green pods.

COMPETITOR (Wheeler and Son), sown May 2, gathered August 8, *period* 100 days. This is a distinct and very fine pea, which always grows taller than any other variety that has been tried here. No doubt it is closely related to Tall Green Mammoth, but it appears to be more robust and productive, and is unquestionably one of the most valuable varieties in cultivation. Messrs. Wheeler state the height to be 5 feet: here it always makes a height of 7 feet at least. The peas are large, a fine colour, and most delicious flavour; one of the best in cultivation.

STRATHMORE HERO (W. Clark), sown May 2, gathered July 26, *period* 86 days. This variety grows 5½ feet high, produces large pods, which contain an average of 6 large peas each. It is a good cropper, and in every respect a first-class pea.

KNIGHT'S TALL GREEN MARROW (W. Clark), sown May 2, gathered July 19, *period* 79 days. This variety grows here 5 feet high, is a good cropper, and produces large, buttery, delicious peas. It is in every respect first-rate.

KING OF THE MARROWS (Sutton and Sons), sown May 2, gathered July 28, *period* 88 days. The plant averages 6 feet high, is highly productive, and long-lasting; the pods are a beautiful green colour, and the peas are good even when old. One of the best tall peas in cultivation.

WATERLOO MARROW (Carter and Co.), sown May 2, gathered July 28, *period* 88 days. This grows about 5 feet here, but in some places it rises to 6 or 7 feet. The pods are produced mostly at the top. A first-class pea.

VICTORIA (Carter and Co.), sown May 2, gathered July 28, *period* 88 days. This sample produced smaller pods than Waterloo Marrow, and grew rather

Thompson's Macdonald.

Branch or Cluster Pea.

Sugar Pea.

and with a distinct black spot (hilum) as in the Egg pea, which is a worthless variety, and the one properly known as "Black-Eyed Susan," whereas Lynn's Wrinkled is a good pea, and should never be described as Black-Eyed Susan, as it is in the Chiswick report of 1867 (*v. Gard. Chron.*, 1867, p. 925). Lynn's Wrinkled is a hardy useful variety, not first-class for the table, but so good in constitution that, all points considered, we are prepared to place it in the first class. The Garden Book contains this entry respecting it: "3½ feet high, peas 4 to 6 in a pod, excellent cropper; a fine dish gathered August 20, when the pods were hanging in beautiful clusters." There can be no doubt that those who supply the London market with peas would do well to give place to this pea, and perhaps the market growers located in the vicinity of fashionable watering places might find greater advantage in its cultivation than those in the neighbourhood of the metropolis.

BRITISH QUEEN (W. Clark), sown May 2, gathered August 8, *period* 100 days. This grandest of peas invariably grows 7 feet high here; in some places it rises to 9 feet, and in others never exceeds 6 feet. But it is everywhere and always one of the best peas known, leafy, robust, bearing an abundance of pale green pods containing 7 to 9 large peas each, which when cooked are elegant, buttery, and delicious. This is a long-bearing pea, but requires a deep moist soil and abundance of manure to be useful late in the season. Sowing late is scarcely advisable, for the plant makes a poor shallow root, and bears too early to be of any use if the seed is sown when the summer is setting in.

CHAMPION OF SCOTLAND, sown May 2, gathered August 8, *period* 100 days. A good tall pea, which usually produces pods of two distinct forms; in fact, a true sample is difficult to obtain. The pods should be long, with a

taller. Yet, all points considered, there is very little difference between them.

NE PLUS ULTRA (W. Clark), sown May 2, gathered July 24, *period* 84 days. The growth averages 6 feet, the pods are of a peculiar dark green colour, and contain 6 to 8 fine peas in each. It is one of the finest peas in cultivation, early as compared with the taller kinds, yet late as compared with any, for in favourable localities it will continue in bearing until stopped by frost. It is one of the most distinct and valuable varieties known.

GENERAL WYNDHAM (W. Clark), sown May 2, gathered July 30, *period* 90 days. This is closely allied to Ne Plus Ultra, but does not grow so tall, and is usually a week later.

ALBERT EDWARD (Barr and Sugden), sown May 2, gathered July 27. A good cropper, and fine quality. Scarcely to be distinguished from Ne Plus Ultra.

MACLEAN'S PROLIFIC (W. Clark), sown May 2, gathered July 20, *period* 80 days. One of the best dwarf peas in cultivation, average height 2½ feet, a good cropper, the peas large and of excellent quality.

MACLEAN'S WONDERFUL (W. Clark), sown May 2, gathered July 20, *period* 80 days. This was reported on from here in 1866 as one of the best peas known. In 1867 it was inferior to Princess Royal, which happened to be near it, and made a very decided contrast in the greater abundance and superior quality of the produce.

MACLEAN'S PREMIER (W. Clark), sown May 2, gathered July 23, *period* 83 days. The growth averages 3 feet, is highly productive, and the peas are of the very best quality. One of the best peas in cultivation.

PRINCESS ROYAL (W. Clark), sown May 2, gathered July 23, *period* 83

days. A first-rate white marrow, growing to a uniform height of 2½ feet, a remarkably good cropper, producing fine large peas, which when cooked are tender, buttery, and delicious. One of the very best.

HARRISON'S PERFECTION (W. Clark), sown May 2, gathered July 12, *period* 72 days. This pea grew vigorously and bore abundantly in 1867, so that if it had been judged as a new variety it would have earned a good character. It is, however, far from first-rate, as, taking a series of years, it is, as a rule, superseded by several other varieties that come in at the same time.

NEWINGTON MATCHLESS (Argent). In the way of No Plus Ultra, but taller and scarcely so prolific. Quite second-rate.

PARADISE MARROW (W. Clark), sown May 2, gathered July 20, *period* 80 days. One of the very best varieties known, average height 5 feet, the pods large, broad, and whitish, well filled; the quality of the peas when cooked first-rate. A most prolific pea, and deserving a first place in every garden.

MAMMOTH TALL MARROW (W. Clark), sown May 2, gathered July 22, *period* 82 days. Average height 6 feet, pods grass-green, large, well filled with large, tender, buttery peas; a very fine variety both in respect of quality and productiveness.

BECK'S PRIZETAKER (Carter and Co.), sown May 2, gathered July 19, *period* 79 days. A handsome pod of a full deep green colour, large, curved, well filled, and making a handsome dish on the table. In appearance and productiveness first-class; in flavour second-class.

WONDER OF THE WORLD (Carter and Co.), sown May 2, gathered August 5, *period* 87 days. This is a fine wrinkled marrow pea, growing 5 to 6 feet high, branching freely, the leaves light green, the pods mostly in pairs, short and broad, and containing an average of 6 fine peas in a pod. Valuable for the lateness of the first gathering and its long continuance in a productive state.

NOBLE'S GREEN MARROW (Carter and Co.), sown May 2, gathered July 17, *period* 78 days. This variety grows 4 to 5 feet high; it is a good cropper, producing handsome pods and peas of a fine green colour.

FLACK'S VICTORY (Carter and Co.), sown May 2, gathered July 26, *period* 87 days. Height 4 feet.

CARTER'S BLUE SURPRISE (Carter and Co.), sown May 2, gathered July 26, *period* 87 days. Height 4 feet.

BLUE SCIMITAR (W. Clark), sown May 2, gathered July 26, *period* 87 days. Height 4 feet.

These three varieties are very closely related. Between Flack's Victory and Carter's Blue Surprise there is so little difference that we may consider them the same. The good old Blue Scimitar differs in the form of the pod, which has a sharper beak than the other two, and in its greater productiveness. Of the three, Blue Scimitar is certainly the best, and a first-class pea for hardness, fruitfulness, good quality, and long lasting. The last dish of this variety was gathered August 14, a *period* of 20 days inclusive.

HARRISON'S GLORY (W. Clark) is an inferior blue pea of the same class as Flack's Victory; it should not now have a place in any garden.

BLUE EXCELSIOR (Nutting and Sons), sown May 2, gathered July 18, *period* 79 days. This variety grows to a height of 5 feet, and produces abundance of handsome pods containing 9 to 10 peas each. This is an excellent second early pea, making a good appearance on the table, and giving a large return to the cultivator.

EXCELSIOR MARROW (Carter and Co.), sown May 2, gathered July 18, *period* 79 days. This variety grows 4 feet high.

As the foregoing two varieties resemble each other in name, and have been substituted one for the other in the making-up of seed orders by the seedsmen, it is proper to point out that the seed of Blue Excelsior is blue and smooth; the seed of Excelsior Marrow is of a uniform pale buff colour, and very slightly wrinkled and pitted. Blue Excelsior was quite green on the 30th of July, but at the same Excelsior Marrow was yellow, and quite past bearing. The exterior skin of the pods of Blue Excelsior is rough and warty; that of Excelsior Marrow is smooth; and to sum up the matter, Excelsior Marrow is as good as Ringwood and much like it; Blue Excelsior lasts longer, and is upon the whole a better variety.

BEDMAN'S IMPERIAL (W. Clark), sown May 2, gathered July 28, *period* 89 days. Height 2½ feet, a good cropper and in every respect a serviceable pea, particularly for market growers.

BURIDGE'S ECLIPSE (W. Clark), sown May 2, gathered July 22, *period* 82 days. This is the dwarfest of the imperial blue peas, the growth averaging 1½ to 2 feet; it is a good cropper, and the peas are fine and handsome; it is therefore admirably adapted for the market grower.

YORKSHIRE HERO (Carter and Co.), sown May 2, gathered July 22, *period* 82 days. Height 2 feet, a middling cropper; not so good this year as last, but useful where dwarf-growing varieties are valued.

THOMPSON'S MACDONALD (Thompson), sown May 2, gathered July 23, *period* 84 days. Average height 5 feet; a robust leafy plant, producing very large, thick, leathery-textured fronds, which are a long time filling, and in the end do not justify the promise they make in the first instance of a good return. Very distinct in every character, and to be tried again.

THOMPSON'S LARGE WRINKLED (Thompson), sown May 2, gathered July 23, *period* 84 days. This variety grew 6 feet high, and produced an abundance of large handsome pods, containing 6 to 7 large peas in each; these when cooked are handsome, tender, buttery, and delicious. This comes nearest to British Queen in appearance and quality, but in this trial was 16 days earlier, and actually promises to be better, and is certainly quite as good, a most important consideration with a variety so early in maturing its pods.

THOMPSON'S GREEN (Thompson), sown May 2, gathered July 26, *period* 87 days. Height 6 feet. A good cropper, pods containing an average of 7 large peas each. This closely resembles Waterloo Marrow, but is forwarder, taller, and a better cropper.

AMERICAN WONDER (Thompson), sown May 2, gathered July 26, *period* 87 days. A robust-growing plant, attaining a height of 6 feet. It is of the first quality, and most closely resembles King of the Marrows, but is sweeter in flavour than that variety.

BRANCH OR CLUSTER (Thompson), sown May 2, gathered July 27, *period* 88 days. This is a mere curiosity of no value at all. It grows 4 feet high, and presents an interesting example of fasciation, several stems being fused together so as to form one flattish fluted stem, which sometimes attains a length of an inch or more. The flowers are produced from the summit of this compound stem, on peduncles which radiate from the centre in a manner which reminds the observer of the ribs of an umbrella. When the pods succeed, the distinctive outlines of the plant are less observable, for it then begins to decay, so that to obtain a dish of peas is not an easy matter, and to save a fair crop of seed next to impossible. This is the "Pois Paquet" of the French gardens.

SUGAR OR EDIBLE-PODDED PEAS, sown May 2, gathered July 22, *period*

83 days. There are in cultivation several varieties of edible-podded peas. They are all characterized by the absence from the pod of the parchment-like lining membrane or parenchyma; the peas are invariably small as compared with the size of the pods, and if they are used at all as food for human beings, they are prepared by cooking them as gathered, in the same way as young kidney beans, but without being cut. A great act of economy is thus accomplished, for pods and peas are eaten together. The common Sugar or Edible-podded pea is here figured; the plant grows 6 feet high, and produces an abundance of large, broad, flat, crooked, semi-transparent pods of extreme thinness, peculiarly marked where the peas within "bulge" out the sides of the pod. This variety is white-flowered.

IMPERIAL SUGAR, POIS SANS PARCHEMIN, MANGE TOUT. This grows 7 to 8 feet high, the flowers are purple, the pods are of immense size, averaging 7 to 9 inches long, broad, flat, much twisted, and "hulged" where the seeds are. It is esteemed amongst the French peasantry, but rarely seen on a good table in France.

VILMORIN'S EDIBLE-PODDED (Barr and Sugden), sown May 2, gathered July 30, *period* 91 days. This grows 4 feet high, and produces an immense abundance of small rather curly pods. If of any use at all, this would be one of the best varieties of peas in cultivation, as it grows luxuriantly on a poor soil, and exceeds almost all other kinds in its extravagant fruitfulness.

KNIGHT'S DWARF SUGAR (Barr and Sugden), sown May 2, gathered July 30, *period* 90 days. Grows 3½ feet high, pods small, but abundantly produced, and not greatly differing in character from the old Dwarf Sugar and Vilmorin's Edible-pod.

These edible-podded peas are held in good repute amongst a certain few cultivators and cooks, and we suppose there is some quality of excellence discoverable in them by those who possess a subtlety of taste and a refinement of discrimination above and beyond the average capacity of mankind. The writer of the last Chiswick report boldly avers (*Gardeners' Chronicle*, 1867, p. 925, last line of report) that "they make a very good and excellent dish." We have given them what we consider a fair trial; they have had all the attention that an experienced cook could bestow, and have been eaten without prejudice, and the verdict in every case has been the same, that they are simply filthy, and unfit for human food. Their appearance is nearly enough to condemn them, but it was never allowed to do so; when the eyes were closed to their repulsive sliminess of appearance, the palate persisted in proclaiming them a compromise between soap and stewed parchment. Why they should be grown or known is to the writer of this report a mystery. But tastes differ, and "every one to his taste" must be the motto in the selection of peas. S. H.

Calendar.

WORK FOR WEEK COMMENCING NOVEMBER 16.

Kitchen Garden and Frame Ground.

ASPARAGUS AND SEAKALE may be forced by the roughest of methods when there are plenty of leaves and large deep pits. Any one can make up a forcing bed, on a plot of spare ground, by means of a few boards to form the boundary of the pit, or turf walls where turf is plentiful. Five or six feet of leaves, without dung, will do very well, and when the roots are planted, rough boards put slope to carry off rain and snow may be used to cover in lieu of glass-frames. During hard weather any amount of dry litter may be heaped over, and a supply of either of these delicious vegetables he had for the mere cost of the roots in the first instance. As ample instructions have been given in this work for forcing these roots, we need not here go into detail; but we mention this rough-and-ready method as a hint to amateurs who want a little work for the winter, and who have no conveniences for forcing by hot water and other expensive methods. Seakale will pay the poor man best to force by impromptu methods, and this should be completely blanched; but asparagus should have air and light when the shoots appear, as it is valueless unless the tops have two or three inches of green growth.

Flower Garden.

ROSES are frequently left in "by the heels" for weeks together at this time of year. It is very bad practice; the frost is sure to get to their roots, and in the event of mild and moist weather they are sure to throw out fresh roots, and those fresh roots are sure to be destroyed when they are removed to be properly planted. Therefore plant at once, tread them up firm, and stake securely.

TULIP BEDS now to have their hoops placed over, to be ready for mats or other covering in case of heavy rains. But the bed should be freely exposed for the present; there is nothing gained by covering too soon.

Fruit Garden and Orchard House.

PLANTING HARDY FRUITS.—The sooner all bushes and trees to be planted are got into their places the better. In forming new fruit gardens, select first the most noted of the established varieties before seeking after novelties. Perfect drainage of the soil is a matter of the utmost importance in districts where heavy loams and clays prevail; but on hot, chalky, and sandy soils drainage is seldom needed. All kinds of fruits require a substantial nourishing soil; apples, currants, and gooseberries will grow well almost anywhere, but better on a good loam in a warm climate than on a bleak sand. All stone-fruits require a good loam, and on well-worked clay generally prosper. Soils containing calcareous matter are, if of good texture and substance, well adapted for the production of fruit; and in preparing old worn-out soils for fruit-trees it would be well to add a liberal dressing of chalk or old mortar.

A FEW REMARKS ON ORCHARD HOUSES.—At this season, when many of our readers will be thinking of adding to their establishments some form of orchard house, it may not be amiss to consider as to whether trees in pots or trees planted out should have the preference. It is possible to deduce facts from failures, which, if properly considered, show us wherein we are in error. We will endeavour to describe a house of trees in what a critic would consider an unsatisfactory state, and one as occasionally seen under the care of a thorough good gardener. If on entering an orchard house, a pale or yellowish hue seems to pervade the foliage, it is a sign of the presence of red-spider, and red-spider is a sure attendant upon starved or suffocated trees, rendering their leanness still worse by sucking from the foliage the juices that should be there elaborated to recruit the stamina of the trees, and enable them to carry their crops to perfection. If badly affected with this

post, the trees often shed their fruit, or if it ripen, it is small and flavourless, the wood of the tree becomes weak and attenuated, and unfit to carry a crop the following year. In such a house a practical gardener would perceive an undue amount of heat, or a dry uncomfortable atmosphere. If he touched the soil in the pots, he would probably find it approaching dryness; besides which he might perceive that the pots were much too small for the size of the trees. If he inquired further, he would find that the trees had not been syringed until the spider had actually made its appearance, and then perhaps not in a business-like manner (a dewing over with the syringe is not enough; they must be battered on all sides, and especially the under sides of the leaves); that they received water at the root by rule, say once a-day, and then, perhaps, in homœopathic doses. On the other side, to go into a house where the trees are well cared for, the foliage is luxuriant, of the colour of a Portugal laurel, the air soft and moist, the trees in pots proportioned to the size of the tree. The soil, whether in the pots or the borders on which they stand, rich and mellow, and perhaps mulched with short stable litter to protect the pots from the direct rays of the sun. If he investigated further he would find that the soil consisted of half-decayed turfs, old cow-dung, and a sprinkling of soot and bone-dust; that water was filtered through soot and cow-dung, to mix at discretion with the soft water which was applied, not by rule, but according to circumstances, once a-week, once a-day, or three times a-day, if they demanded it; that as much old soil as could be removed from the top of the pot, without injury to the roots, was every winter removed and fresh supplied. That the trees at the same time were dressed with a mixture of soft soap and sulphur, and the walls washed with lime and sulphur; further, that green-fly had been carefully looked for in spring, and, the moment it was perceived, syringed with tobacco-wash, or fumigated with tobacco paper. That the blossoms had been brushed over with a soft brush to distribute the pollen, and thus secure the setting of a regular crop of fruit, and that the fruit when thus set had been early thinned, so as not to waste the energies of the trees. That cold winds and severe frosts had been denied free ingress, by closing the ventilators on the windward side; yet that perfect ventilation had never been omitted when it could be safely permitted; that the syringe, or what is better, a small engine, had been constantly used every morning (since the setting of the fruit), when there was a prospect of a clear day; and again every bright and warm afternoon, just before the sunbeams ceased to play upon the house. Our readers will be enabled now to judge how far their practice has fallen short of the above, and perhaps feel appalled at the amount of attention apparently necessary to perfect success in the pot-culture of fruits, yet the attention is necessary, and it is attention to the minutiae that makes the successful gardener. This many amateurs cannot find time for, hence there is something wanted to enable persons so situated to reap a crop with greater certainty than by the pot-system. The plan we propose is to plant out the trees in prepared borders, so as to render them less susceptible of injury from slight neglects; the plan is by no means new; it has been advocated by several writers, and is practised by many of the best gardeners of the day, but usually in houses of greater pretensions than such as are commonly known as orchard houses. The difference, however, is not so much in the make or size of the house as in the preparation of the border, the form of the house mattering but little, so long as no fundamental principles are violated, and these are—a situation open to the south or thereabout; glass to the ground, or nearly so, that all the light possible may be admitted, and plenty of opening ventilators, that there may be no

ack of air when required. These points are fully kept in view in the accompanying sketch, and such a house could be erected at as little cost as it is possible to produce an efficient structure. It is set upon nine-inch brick foundations, which rise nine inches above the ground level. Upon these a plate of oak timber is laid; into this deal studs, three feet apart, are morticed, and on them again, at the height of five feet, a plate of deal is laid to receive the rafters and astragals, or bars into which the glass is glazed. The superstructure at the top is for the purpose of giving air, and is composed of thin boards, the two side ones hung on joints, and having a lever screwed on the inside, to which a string is tied, and carried down behind a pulley to the side of the house, for the purpose of pulling them open. Every alternate light between the side studs is made to turn upon pivots for the purpose of giving air. The width of the house inside is sixteen feet, and the height eleven feet. A represents a drain laid along the centre, in case water in excess should find its way in, and on each side of the drain is a layer of brickbats, rammed down to prevent the roots of the trees reaching the subsoil. B, the border, from two to two and a half feet deep, of good fresh soil, composed of half-rotted turfs from a field. C, spine racks to walk upon. These should be made in convenient lengths, that they may be removed in case a tree requires lifting, &c. D, espalier peaches and nectarines on the south side, and figs and plums on the north side. E, standard peaches and nectarines. By such an arrangement as this, all other things being equal, a great quantity of fruit would be produced in a small house. The amount of care and attention necessary would be far less than

it would be to carry out in good style a house of pot-trees, and the risk of spoiling the crop from occasional neglect much less, as the trees are in a more natural position, and therefore I am induced to recommend its adoption. It must not be forgotten, however, that the border, being under cover, receives no moisture from the atmosphere, therefore abundant watering will be necessary, especially when the trees are swelling a crop of fruit. But then one good watering will suffice for several days, whereas a man that has a house of pot-trees must always be watching them. The same attention to airing, syringing, and setting the fruit blossom, pinching back shoots that are not required to form the tree, &c., will, however, be necessary as well in the house where trees are planted out as in that in which the whole are in pots.

Greenhouse and Conservatory.

KEEPING OUT FROST—TEMPERATURE OF THE SOIL.—A few words on the principles which the gardener should keep in mind in his endeavours to keep out frost may be seasonable just now, for it may be questioned if gardeners have invariably a clear view of the object to be gained, and the best means of securing it; and those among our readers who are familiar with the theory of the subject will not mind seeing a few commonplace facts set forth for the benefit of those who have yet something to learn on the subject. The leading principle of all protective measures may be stated to be not so much keeping out frost as keeping in heat. If any one will take the trouble to examine a bed of snow when it has lain upon the earth a day or two, it will be found that, however hard frozen on the surface, it is actually thawing where it rests upon the earth. If the snow be very thin, this may not happen to be the case, because the cold air may penetrate through it, and cause it to freeze to the soil; but when deep snow has lain some time, it invariably begins to thaw next the soil, however hard it may freeze at the surface exposed to the atmosphere. Another lesson of value may be gained just now by dipping some water from a well; it will come up comparatively warm, and its temperature probably 40° to 50°, according to the depth and the soil. The inference from these two observations is obvious enough: the earth is a reservoir of heat, and this heat it is the gardener's business to make the most of, and all protective measures should have for their object to prevent its escape. This earth-heat is a matter of some importance to the life of plants when its amount is considered. This heat is constantly rising to the surface; hence, if we pile up a mass of material of any kind, and leave it for some days, however hard it may get frozen, it will be found that when removed the earth is quite warm on the spot it has covered, a simple consequence of the heat having been confined. The heat of the earth varies very much near the surface as the seasons revolve, but the deeper we descend the less is the variation. It is especially worthy of notice that the soil is such a bad conductor of heat that even at very trifling depths the variations do not keep pace with the changes of atmospheric temperature, and this leads to very interesting results. By the elaborate experiments of Professor Forbes it was shown that at three feet the greatest cold does not occur till February; at six feet, not till March; at twelve feet, in April; and at twenty-four feet, in July. These facts explain why water from deep wells is (as people say) cold in summer and warm in winter. At a depth of two feet the temperature usually rises considerably from the middle of April to the middle of July, and is in some seasons subject to many fluctuations; but during autumn and the early part of winter much of the heat absorbed during summer is retained by the crust, and plants exposed to severe frosts are still warm at their roots, and the atmosphere is so far affected by the radiation of heat from the earth that early frosts are considerably modified in their effects. Now the grand object should be to get as much of this heat as possible, and to keep it. For this purpose we use frames, the glass coverings of which obstruct the radiation of the earth's heat, and preserve the plants from the severities of the atmospheric temperature. When frost comes, we lay on the frames such things as mats, straw, &c., and these still further obstruct the radiation, and prevent the cold winds gaining access to the frames. Everything that can be used to counteract radiation may be turned to account, but there is a good and a bad way of doing it. It so happens—and every gardener should keep the fact in mind—that the atmosphere is a tolerably good non-conductor, and a body of air shut up close cools very slowly. It is also to be borne in mind that water is a good conductor of heat, and hence cools quickly, especially at the surface. Suppose we really want (which we never do) to cool down the atmosphere of a frame without taking off the light, the best way to do it would be to throw water on the glass; the evaporation from this during wind or sunshine would probably soon render the air inside the frame colder than the air without, and at night the frost would act upon the wet glass and carry on the cooling process, and if mischief were intended it would be effectual. The rationale of this process is that the heat from the soil and atmosphere of the frame is conducted outwards and dissipated. We learn another lesson from this, namely, to keep the glass, the mats, the straw, and whatever else is used for covering, as dry as possible, and at any time when they are unavoidably wetted they should be taken off and dried at the first opportunity. But we have not yet done. The air is a good non-conductor; hence, if a mat or tarpaulin can be stretched over a frame and fixed down close at the sides, and the superficies kept at a few inches from the glass—as by laths for instance—there will be a stratum of air between the tarpaulin and the glass, and this will be as good as another thickness, or, to use a homely phrase, will make the frame a coat warmer. In very cold countries, travellers prefer cloaks to coats; loose garments are found to be warmer than tight ones. The reason is that they enclose a considerable body of air, and this being a non-conductor adds to the comfort of the garment. Now, in covering up, loose litter is found very effectual, and, *ceteris paribus*, the looser it is the better. A great heap of dry straw thrown on over a mat will do wonders to keep out frost, because the straw has entangled in it a vast amount of air, which renders it non-conducting. Any light dry material, such as waste wool, clippings of hedges, withered tops of chrysanthemums, &c., may be made use of in the frame-ground during hard frost. A few more hints may be of service, especially to young gardeners. During frost every plant in a pot—no matter if the hardiest plant known—should have its roots protected. If exposed so that the roots get frozen, death is likely to be the consequence. One of the best materials in which to plunge potted plants, whether indoors or out, is the now famous cocoa-nut fibre refuse. This is never very wet, and never quite dry, and is such a non-conductor that the frost rarely penetrates more than a few inches below the surface, and it may be heaped round the collar of a plant that needs extra protection without any fear of harm, provided it is removed on the return of mild weather. Lastly, plants exposed to very low temperatures need not of necessity be exposed to light. We have known pits full of geraniums to be buried under heaps of litter for three weeks in complete darkness without taking the least harm. Of course, on the return of mild weather, light

should be admitted as soon as possible. In case of plants getting badly frosted, let them thaw slowly, and in the dark. Gardeners sometimes make a rush at the fire when they find frost in the house, and by getting up too fierce a heat, do more harm than if they had left things alone. Beware of extremes, and aim at making fires burn steadily and continuously, rather than at a pace that is likely to roast the inmates of the house.

Stove and Orchid House.

ORCHIDS are so generally at rest now that this is the most convenient season for a general examination of the stock, and the renewal of blocks, baskets, &c., for improving the effect of the grouping and arrangement. Repot any that require it, and let every plant undergo an examination, during which the surface material should be wholly or partially removed.

Forcing Pit.

PEACHES to be forced need now a thorough dressing; clean the house, prune the trees, tie in and wash the stems and branches with a paint made of clay and Gishurst; mulch the border, and give it a thorough good soaking with tepid water. Give the trees air on fine days, but shut up at night. This treatment will bring the roots into action in advance of the branches, and when the trees are started they will make safe and healthy growth.

PINES require very careful management now, for we have warm sunshine one day, and perhaps fog and frost the next. There ought to be a command of more heat than is absolutely required, which is easy enough with hot water, but not so easy with fermenting material, so as to keep the temperature of bottom and top pretty uniform, in spite of changes of weather. As a comparative state of rest will be good for all classes of pine stock now, a bottom-heat of 65° for a minimum, and 70° maximum, top-heat 55° minimum, and 65° maximum, will be the safest for the plants. Supply water according to the state of the weather; take advantage of bright open weather to water pretty liberally, raising the heat and giving air at the same time; and when frost and darkness recur, withhold it as long as will be safe, but not to cause exhaustion.

CUCUMBERS to be kept safe as to bottom-heat, or they will begin now to drop their fruit, or to show canker at the collar. Be prompt, therefore, to renew the linings, if needful, where fermenting material is used. Recently-collected leaves will, with the help of dung once turned, yield a very steady heat, and the better in large masses.

FORCING.—Refer to notes of the past few weeks, give plenty of water to plants that have started away well, and syringe with tepid water on bright mornings, giving air afterwards when the leaves are dry. Beware of high night temperatures; beginners in forcing invariably make their first mistake in using too much heat at night, and the consequence is spindling growths and ill-developed flowers.

VINES grown in pots for forcing for early grapes may now be shifted into large pots, and the safest way to do it will be to shift pots and all, and without turning out the roots of the vines. Prepare the 12-inch pots with crocks and a few inches of compost; enlarge the drainage holes of the pots the vines are in, then place these pots inside the larger pots, and fill in with tough turfy compost; the outer pots will soon be full of roots, and the vines may be allowed to carry all the bunches they show, and when these are ripe the vines should be destroyed. Vines to rest from this time to be pruned at once; in fact, early pruning is the only safe method of preventing bleeding.

Correspondence.

LONG-CONTINUED EXHIBITIONS.—I have read with considerable interest the discussion which has been going on in the Magazine respecting the pelargoniums shown at Manchester by Mr. J. Wills and Mr. J. Watson. But, sir, as you have expressed a hope that there will be no more correspondence on the subject, I will not trouble you or your readers with any remarks of mine on that point. But it seems to me that the discussion gives rise to the question, whether exhibitions should be continued for such a length of time as that occupied by the late Manchester Show. We are apt to jump from one extreme to the other. We have been in the habit of holding shows of one day's duration; now we leap at one bound to *nine* days, which of course includes one Sunday. It is not reasonable to suppose that the owners of choice, rare, or new plants will consent to allow them to remain for eight or nine days in an exhibition house or tent. Cold draughts from doors or openings, a dry atmosphere, and sometimes lots of dust, will injure, if not spoil, tender plants that have been nursed with every care in proper structures. But these choice things are just what the public want to see, and also what proprietors wish to show. Hence special arrangements are made with committees and managers of shows, to the effect that, provided they will allow such and such things to be removed after the first or second day, then they will exhibit them. Now, I know that this is done, and that it was done at the late Manchester Show. Mr. Wills admits that he removed his best geraniums; but Mr. Toll also removed the collection of twenty orchids which had received the first prize of £20. And this made a much more serious gap than the exchange or substitution of a few pelargoniums. Now I do not blame Mr. Toll for removing his splendid plants, for those not so removed cut a sorry figure by the end of the ninth day. But then we must not be too hard upon Mr. Wills for doing the same thing with his plants, because what is right and fair for one exhibitor is equally so for another. Now Mr. Editor, I always think it best to steer midway between two extremes. One day's show is not enough for societies—it does not pay. Eight or nine days is too long for exhibitors—it spoils their plants. Then say *three* days, and not allow any plant to be removed till the end of the show, and treat all exhibitors alike. A MANCHESTER GARDENER.

THE PARADISE AND QUINCE STOCKS IN ENGLISH GARDENS.—On the subject of the discussion on the cultivation of fruits, the following letter has been sent by a well-known cultivator to one of the disputants: I had not read two lines of the critique by "Fruit Cultivator and Traveller" before I settled in my mind who the man was. *This is his system of advertising* whenever any one dares to touch upon "fruit-growing," especially upon some pet points, guarded over by what we might aptly call the Cerberus of fruit-growing on quince or paradise stocks, orchard houses, or cordon training, things he has taken under his special protection, and we be to the adventurous cultivator that dares to differ with him! Down he comes, like a great spider upon an unlucky fly. The gardeners in our parts call him "The Fruit-tree Spider," and say, "Oh! another of his long advertisements, based upon the fact that he has something wonderful in the way of fruit-trees, fruit-tree stock, or his 5,000 Louise Bonne pears, which he has held up to the public

twenty times as being the *ne plus ultra* of fruit-growing." Although a little while ago, in his controversy with me about quince stocks, he said that the 5,000 had taken the yellows, and had been put into quarantine, they are now let loose upon you, and to charm the public ear as something that is worth everybody's attention in the way of making a fortune; in fact, it is like the folks who offer a large fortune for a small sum. Send one penny stamp, and I will tell you how to clear £1000 per annum, *i. e.*, "Plant Louise Bonne pears, and buy them from me, and quince stocks. *I have the largest stock of these trees in Europe.*" This was the exulting climax to one of his broadsides against somebody not long ago, who dared to say something against quince stocks. Holding the largest stock in Europe (??), no wonder "Mr. Spider" slid with electric rapidity down his line on the head of such an intruder. I dared to differ from him, or at least his ally, Mr. —, about the paradise stock. They both declared it to be too tender for England (!!), and were tacitly supported by the editors of —. (I send you the numbers, that you may see what the parties said.) Now, the Pommier de Paradis stock will live where no other apple-tree except the Siberian Crab will live, but it will *not thrive in dry warm soils*. Like the quince, it soon perishes in such; they are both admirably calculated for wet or heavy soils, but in such a winter as our last, 1866-7, the quince, unless where its junction with the pear was covered two or three inches with soil, suffered in damp places very much. I lost hundreds of trees that were not covered as above; *but not a twig of the paradise was hurt*, although only a few yards separated the quince from them. It is just perfect willing blindness, brought on by having another kind of stock to sell, that could cause any man to say that the Pommier de Paradis is tender. I enclose a letter from M. Decaisne to me, in which you will see that the learned Professor said, "Il ne gèle pas." I said the worthies who had combined to destroy it might roast it, but they could not freeze it to death. I send you some stocks and a few apples worked on it, to show you how well they grow upon damp soil, not saturated. I have an old tree planted under the end of a spout which conveys the water from the roof of a vinery. It *thrives and luxuriates*; it is in imitation of the natural habitat of the plant in the Caucasus. The tree bore two dozen of fine, deliciously-flavoured, aromatic fruit this season; but they must be eaten from the tree, otherwise they lose their flavour in two days. I find that all the large apples grow freely and bear abundantly when grafted upon this stock, and that the fruit partakes of its fine aromatic flavour, generally speaking. Many are much larger than from crab stocks, and all the small-growing kinds bear so that the trees are exhausted in 12 to 16 years. This might be remedied by timely thinning. I have sent you a paradise stock in which the bud was killed by the cold, to show you how well the stock grew after. We had hundreds of crab stocks injured, and I have enclosed a piece of an apple-tree, to show what havoc the severe frost makes with some kinds of apples. Many pear trees were split right through. To look at the apple branch, you would think it was canker produced by the soil. I do not think that trees canker much from the soil being uncongenial, but that the greatest portion of cankered trees have become so from having been frozen. I have hundreds of trees so destroyed, all of which were in perfect health before the frost. I never saw a paradise stock hurt; but it must be borne in mind that, like the quince, it is useless upon dry and warm soils.

Replies to Queries.

Z. Z.—You are quite mistaken. If we replied privately to all who ask for replies that way, one month's work would complete our labours. We do not engage to write privately to anybody.

J. R.—The bulbs of *Lilium auratum* may be left in the ground all winter, but it would be advisable to heap a small cone of coal-ashes or sand over them. We cannot encourage you to attempt keeping fuchsias and geraniums all winter in a trench out of doors with boards over them. We would rather advise you to throw them away, and thus save yourself trouble and disappointment.

Constant Reader.—In the absence of information on the construction of the furnace and flue, we cannot point out a specific remedy, but we can offer a hint that may prove valuable. Devise some means of warming the flue quickly prior to properly lighting the fire. Burn shavings, crumpled paper, straw, and other light stuff, to force a body of flame into the flue, and, probably, if the fire is properly lighted while the flue is warm the evil complained of may be remedied.

Subscriber will find practical papers on the treatment of pot roses in the numbers for July 22, 1865; October 21, 1865; December 8, 1866; and March 30, 1867.

T. C.—We know nothing of the stove you inquire about.

Young Beginner.—Caladiums must be kept rather dry, and in a temperature of about 40° while resting. *Pilea muscosa*, the "artillery plant," must be kept in the stove during winter, but will do very well in the greenhouse in summer. The *Aristolochia* sp. is probably a stove plant; but we cannot say for certain, unless you can give the specific name or the native country of the plant. *Chamærops humilis* will do better in the greenhouse than the stove. We are not acquainted with all the geraniums you name, but we can advise you to do justice to Dr. Lindley, Eleanor, Beauty of Oulton, Provost, Editor, and Le Grad. Beauty of Brixton is not good enough for exhibition, but is valuable for early flowers.

Westmoreland.—An amateur is one who cultivates plants for his amusement solely, as distinguished from one who grows them for sale, or who is employed in the capacity of a gardener. The interpretation of the term varies in different places; as, for example, at the great London exhibitions gentlemen's gardeners are considered amateurs; in the country another rule prevails. Your vines want the help of heat during April and May.

Friend.—It is the rule, and not the exception, for recently-purchased male aueubas to flower in November or earlier. It is owing to the artificial treatment they have been subjected to, and which the trade are compelled to adopt in order to multiply them rapidly. After you have had it one full season in the open air it will flower at the same time as the females, but you must keep it in the greenhouse the first winter. The pollen should be brushed off daily into a sheet of tinfoil, or a dry box of some kind, and it would be well to spread tinfoil over the soil in the pot to catch all that falls. If kept dry its vitality will be preserved, and it may be applied to the female flowers when they are ready to receive it in the spring. It is advisable to place the female plants under glass, for better convenience of fertilizing—that is, if they happen to be in pots.

T. Peachey.—The large-leaved plant is *Begonia semperflorens alba*; the small-leaved plant is *Begonia grossulefolia*.

The Gardener's Magazine.

SATURDAY, NOVEMBER 23, 1867.

CLEMATIS JACKMANI is undoubtedly a true hybrid, and the type of a new race of ornamental plants. It was originated by Messrs. Jackman and Son, of the Nurseries, Woking, by crossing *Clematis lanuginosa* with *C. Vitiella* in the first instance, but possibly subsequent crosses of the progeny were made with the aid of the pollen of *C. carulea*, and we have sometimes thought we could detect the parentage of *C. campanuliflora* in the race. Messrs. Jackman have not published any account of their operations; and while great commercial interests are bound up with their work, it would perhaps be unreasonable to expect them to relate in detail the several stages of the process by which at last they have originated a distinct and most valuable race of flowering plants. It will suffice for the present that the forms and colours of the flowers of this race are new to our gardens, and surpassing in splendour by many degrees the handsomest of the hardy clematises hitherto known to cultivators. This race offers elements for decorative purposes which are certain to be appreciated; for the majority present us with shades of blue, which are scarce, and the flowers are, generally speaking, so large and so abundantly produced, that in respect of their colours they have no parallel amongst garden flowers at the season when they are at their best, in the later part of the summer and throughout the autumn. Nor is it a small consideration that this race is as hardy as its parents; we are inclined to believe some degrees more hardy, for the last severe winter did no harm to them in places fully exposed. And in respect of relative hardiness, it is worthy of observation, that so long as the roots of the plants are not destroyed, the destruction of the wood is but a small loss, in the event of a winter severe enough to be mischievous to that extent, for the roots will throw up new shoots in just the same way that own-root roses do, and, as almost any hardy plant will do, renew itself from the root, if not budded or grafted. These clematises, varieties of the hybrid Jackmani, merit attention not only as superb ornaments for walls, trellises, rockeries, and other places where climbing plants are required, but also for planting in large beds to make grand masses of blue, purple, and crimson, the plants being trained out and pegged down to produce an even sheet of leaves and flowers. Since bedding has become in great part a system of repeating *ad nauseam* a few generally approved formulæ, it is matter of thankfulness to be tempted by the offer of a new race of plants to go out of the beaten track, and attempt something new; and assuredly these varieties of clematis will give a new and fresh, and perhaps surprising, tone of beauty to the parterre wherever they are generously dealt with. Nor should we forget what may be done with them as pot-plants. Messrs. Jackman have demonstrated, by the specimens they have presented at several of the exhibitions held at Regent's Park, that these plants may be grown in pots to such perfection that shall find but few, even amongst the vast variety of stove and greenhouse plants, to equal them. Certainly some of their exhibition specimens have been glorious for contour, complete furnishing, and abundance of splendid flowers.

To develop the beauties of these new varieties to the utmost, a light rich soil is requisite. A warm position is better than a cold one, yet relative climate is not of such great importance as full exposure to sunshine and a tolerably dry subsoil. Every kind of clematis is at home on chalk, and probably in many gardens on the chalk, where some favourite bedders make but a poor figure, these plants would prove of great value, if assisted with good manure and leaf-mould to give them a fair start in the first instance. To turn them to the best account as bedding plants, they should be grouped in large beds, or in clumps on borders, the plants being put at a distance of from two to three feet apart, and to be pruned back rather close every year. Their brilliant shades of maroon, purple, and purplish crimson cannot be equalled by any other race of bedding plants; and wherever and whenever they are seen, they will be renowned and remembered. As this is a good time as any to plant these clematises, we subjoin a select list of a few of the varieties amongst the very many we

No. 134, NEW SERIES.—VOL. X.

have seen from time to time and reported on in these pages. All are Jackman's except those with names of raisers attached:—

- C. Jackmani*.—Flowers 6 or 7 inches across, velvety violet-purple; a magnificent hybrid.
- C. lanuginosa pallida*.—Flowers fully expanded, the colour lilac, with reddish bars down the centre of each petal, or, to speak with strict technicality, sepals.
- C. rubro-violacea*.—Flowers velvety reddish tinted violet; remarkably beautiful.
- C. Vitiella amethystina*.—The flowers have curled petals, and are of a pale violet-blue colour; very beautiful.
- C. Vitiella Moorvana*.—Very closely resembling *C. Vitiella* in the form of the flowers; colour deep violet.
- Prince of Wales*.—Flowers deep purple with red bars. The whole series should have been named as florists' flowers, as this is, instead of in dog Latin, which is bad enough for botanical curiosities, but for useful garden plants unendurable.
- Magnifica*.—Very large and finely-formed flowers of a soft purple colour, each petal having a sharp bar of red down the centre, producing in the flower the appearance of a four or five rayed star.
- Velutina purpurea*.—Large flowers of a beautiful maroon-purple colour.
- Rubella*.—A very fine variety, producing abundance of flowers, and which have generally five or six petals; the colour velvety claret shading to black; a grand, massive, and sometimes astonishing variety.
- Lady Caroline Neville* (Cripps).—Delicate lavender with dark stripe.
- Tunbridgense* (Cripps).—Reddish purple with blue stripe in the centre of each petal.
- C. lanuginosa candida* (Bull).—A pure white-flowered variety of the beautiful *lanuginosa*.
- C. azurea (carulea) reginae* (Henry).—Flowers deep mauve or pale violet colour, usually with six to eight petals; fine.

Any of our readers who can find amusement in searching through our reports, especially for the years 1864-65, may enrich their lists of choice varieties of *Clematis* with others besides those enumerated above. We have only directed special attention on the present occasion to such as we happen to be able to speak of with confidence, after some experience of their cultivation. It is quite possible, and we think highly probable, that the varieties we have no practical knowledge of may be quite equal in beauty to those above described.

THE HIBBERD TESTIMONIAL.—This has been wound up, and the presentation made to Mr. Hibberd in just such an elegant and considerate manner as the friends of the recipient expected and desired. Mr. Hibberd will, no doubt, embrace the earliest possible opportunity to return thanks.

THE FINDLAY TESTIMONIAL.—The subscriptions to this fund amounted to £246 17s. 6d. The expenses of printing, collecting, &c., were £30 11s. 6d. The remainder was bestowed in providing a presentation plate, which cost £6 6s., and filling a purse with the balance, £210. The presentation was made ten days ago, and Mr. Findlay acknowledged the compliment in the graceful way that is his wont; and an affair, creditable to all concerned in it is thus agreeably terminated. "Worth makes the mau," &c.; therefore, to set a price on Mr. Findlay's labours and talents is impossible.

HARDY HERBACEOUS PLANTS are fast rising in popularity, and it is no doubt quite reasonable that the "Garden Oracle" for 1868 contains lists of selected varieties comprising the best known in every class, and numbering in all about 500 species and varieties. The editor will challenge the wise in such matters to find in his selections a single bad or even second-rate (of its kind) species or variety in the whole of the list.

THE ROYAL BOTANIC SOCIETY intend to take the lead in the exhibitions next season, and will probably startle the public with a great exhibition in the very dawn of spring.

THE TRIALS OF VEGETABLES AND ROOTS at Stoke Newington, and in respect of which reports on peas, lettuces, onions, &c., &c., have been published, will be continued until every class of vegetables and roots of which there are many varieties have been thoroughly revised. The Stoke Newington collection of potatoes is probably the largest ever made, comprising in all about 200 varieties; this will form the subject of a report shortly. When these reports are completed, we shall endeavour to reduce and classify the varieties, with a view to abolish bad and establish good sorts, and settle all existing difficulties of nomenclature.

THE FRENCH RAT-TAMER.—The most popular of the shows of the season at St.-Cloud fair has been *l'homme aux rats*. The name of this Rarey of the rat race is Antoine Leonard. His sole theatre is a sort of perch, which he sticks into the ground, and then he takes his *corps de ballet* out of his pocket. At his word of command the rats run up and down the perch, hang on their legs, then on two, stand on their head, and, in fact, go through a series of gymnastic exercises that would put Blondin himself to the blush. His crack actor is a gray rat he has had in his troupe for eleven years; this old fellow not only obeys Leonard, but is personally attached to him. It is a curious sight to see Leonard put him on the ground, and then walk away. The creature runs after him, and invariably catches him, however many turns he may make to avoid him. An Englishman offered 50f. for him about two years ago, but Leonard would not separate from his "old and attached friend."

Exhibitions of Chrysanthemums.

MR. SALTER'S EXHIBITION OF CHRYSANTHEMUMS.

Mr. Salter's exhibition, like every other of the kind, is this season some degrees less brilliant than we are accustomed to, many of the new varieties being undeveloped at so late a period as the 16th, when we made a call for inspection. To be sure, there are plenty of flowers, and folks who go to be amused, or whose business it is to pick up notions practical, will not be disappointed. As regards the new varieties, however, it is scarcely likely they will be in a fair state for judging of their merits till quite the end of the month. The old lean-to is very gay with established varieties, and Mr. Salter takes care to sprinkle amongst the finished show flowers of the incurved section a few of the dashing reflexed and tassled kinds, to vary and enrich the display; for as conservatory flowers these are of great value, as they are not only, generally speaking, rich in colour, but they break up the monotony of the very formal exhibition of flowers. Particularly noticeable for their fine colours are, Bixio, Chevalier Domage, Prince Albert, Compactum, Rose Leech, Alma, Annie Salter, Christine, Invincible, Julia Grisi, Jewess, Pelagia, Pagne, Julia Lagraverre, Lord Clyde, Madame Poggi, Madoua, Maréchal Niel, Mount Etna, Mr. Murray, Prince Consort, Quilled Beauty, Superbe, and White Christine.

In the incurved section, the most striking for beauty of form and colour are Venus, Prince Alfred, Prince of Wales, Queen of England, Jardin des Plantes, Gloria Mundi, Beverley, Golden Beverley, Mrs. George Rundell, Hereward, John Salter, Aurea multiflora, Dido, Dr. Brock, Dupont de l'Eure, Formosum, Garibaldi, General Harding, Golden Ball, Golden Queen, Lago, Lady Harding, Little Harry, Lord Palmerston, Mr. Brunles, Mrs. Haliburton, Rev. J. Dix, Robert James, Sir Stafford Carey, Trilby, Vesta, Yellow Perfection.

In the second house, or top of the T which constitutes the "winter garden," Mr. Salter has a great batch of seedling Japanese chrysanthemums. These are mostly of the "dragon" class, the florets being set round the central disk like wires, in some cases stiff and straight, in others curled and twisted in a most fantastic manner. A considerable number of these will be destroyed, but a selection has been made of a few that will be valued for conservatory decoration. Generally speaking, these Japanese varieties flower very profusely, and some of the plants here are literally smothered with flowers. One that had been condemned for a certain flimsiness of petal, and poverty of colour, was literally a heap of flowers of a cheerful tone of pale lilac, and if it had but some degree of substance would be a marvel amongst Chrysanthemums.

The collection of variegated-leaved plants at this nursery is admirably kept up, and has of late been largely reinforced. One of the most remarkable plants in the place, and, in its way, one of the most remarkable plants ever seen, is *Beta chiliensis*, a gigantic species, with ample, deeply-wrinkled, black-bronze leaf, and thick stem and mid-rib of the most intense carmine or of a yellowish scarlet colour. The growth of the plant is free, and it appears to be more hardy than the common beets of our gardens, as on the 16th a plant stood in the open ground unhurt: this, however, may be owing to the shelter afforded by the closely adjacent walls and buildings. Mr. Salter has but some half-dozen plants, and from these he hopes to raise a few seeds next year. This beet makes a mere spindle of a root, and is apparently only worth consideration for the splendour of its leaves; but it may just happen that the fleshy stem contains sugar enough to render the plant valuable for manufacturing purposes. Another meritorious novelty is a new variety of *Canna* called *Maréchal Vaillant*, which has peculiar narrow pointed leaves which are heavily striped and shaded with purplish bronze on a dull green ground. It is certainly one of the best for the beauty of its leaves. *Dahlia imperialis* is coming into bloom, or, at all events, a large plant in the show-house has half a dozen or more flower-buds of the size of marbles on it, but it is quite a question if the temperature is sufficient for their full development. If transferred to an intermediate house, the plant would probably flower perfectly.

The following are the new varieties seen in flower during our visit:—

Baron Beusi (Salter).—A large incurved flower of fine quality, the colour chesnut with gold points outside, but on the inner side the petals are reddish chocolate.

Lord Derby (Salter).—A superb large incurved flower, in the way of Prince Alfred, but quite distinct; the colour is rich dark claret turning over silvery purple; first-rate.

Captivation (Salter).—Not incurved, and like a dahlia, colour puce pink with tinge of orange in the centre; a lively pleasing variety, well adapted for the conservatory and to grow as a specimen plant.

Golden Orb (Salter).—Large incurved, clear canary-yellow.

Golden Thread (Salter).—A Japanese variety; a large, curiously quilled flower, looking as if formed of stiff golden wires set on a central disk, very early, and highly decorative.

Aurantia (Salter).—A Japanese variety, buff yellow, handsome.

Tarantula (Salter).—A Japanese variety of remarkable form, more nearly resembling a gigantic spider than a flower of any kind; the wiry or thread-like florets radiate from a button-like disk; they are at first yellow, but afterwards change to purple.

Meteora (Salter).—A Japanese variety, of a fine orange colour.

Tycoon (Salter).—A Japanese variety, the flower very large, colour fine cinnamon inside, the back golden.

STOKE NEWINGTON.

The twenty-first exhibition of this society took place in the school-room opposite Abney Park Cemetery—a roomy and well lighted apartment admirably adapted for the purpose. It was in every respect satisfactory, though here as elsewhere many of the best specimen plants were scarcely in full flower, the season being unfavourable. The plants were arranged so as to form a continuous bank all round the room, those on the platform at the head of the room being improved in appearance by the intermixture with them of some bright green ferns and other elegant plants.

PLANTS.—The best group of six plants on this platform came from Mr. Adam Forsyth, of the Brunswick Nursery, Stoke Newington, who took the first place in the class for six. Mr. Forsyth's plants were Alma, Lady Harding, Golden Christine, superb; Annie Salter, Vesta, Dr. Sharpe; this is one of the richest in colour of all known chrysanthemums, and deserves to be everywhere grown for the conservatory and exhibition. Second, Mr.

George, with noble plants, rather less forward in respect of bloom than those of his more successful rival. The varieties were St. George, Vesta, Christine, Prince of Wales, Golden Christine, Annie Salter. *Six pompones*: First, Mr. Butcher, gardener to C. Ballance, Esq., Lower Clapton, with White, Golden, and Lilac Cedo Nulli, Hélène, Andromeda, Bijou d'Horticulture, neatly trained and with plenty of flowers. Second, Mr. A. Forsyth, with White Trevenna, finely formed; three Cedos, a Carrobert, and a Duruflet. *Three plants, large*: First, Mr. Drain, nurseryman of Kingsland, with very fine examples of Vesta, Christine, and White Christine. Second, Mr. George, with Golden Hermine, Prince Albert, and Lady Harding, all admirably grown, but scarcely forward enough. Third, Mr. A. Forsyth, with a splendid plant of Dr. Sharp, glowing with colour; Golden Christine and Annie Salter. *Four plants, large*: First, Mr. Drain, with Christine, White Christine, Golden Christine, and Lord Ranelagh. Second, Mr. Shield, with Annie Salter, poor; Beauté du Nord, Vesta, faulty; Christine. *Three pompones*: First, Mr. Butcher, with Salomon, Golden Cedo, and Andromeda. *Six pyramid pompones*: First, Mr. Butcher, with Lilac, White and Golden Cedos, Salomon, Andromeda, St. Thais, all in good growth and training, but backward in respect of flowers. *Six standard pompones*: First, Mr. A. Forsyth, with pretty plants of Lilac and Golden Cedos, Calliope, Andromeda, Bob, and Mr. Astie. Second, Mr. Butcher, with Brown, White, Golden, and Lilac Cedos, Bob, and Salomon. *A miscellaneous collection*, put up by Mr. A. Forsyth, obtained, as it deserved, the very fancifully-painted and well-built wheelbarrow offered by Mr. Shepherd, coach-builder, of Stoke Newington, for the best group. In this collection we noticed as particularly good, Duruflet, Rose Trevenna, Cedo Nulli, Prince of Wales, and others.

CUT FLOWERS, best 24, Mr. Slade, of Kingsland, with Novelty, Prince of Wales, Golden Beverley, Madame Lebois, Cherub, King of Denmark, Golden Dr. Brock, Lady Harding, Aurea multiflora, Cassandra, Rev. J. Dix, Duchess of Wellington, Orange Perfection, White Formosum, Yellow Formosum, White Globe, Gloria Mundi, Lord Ranelagh, Prince Alfred, Beverley, General Bainbrigge, Jardin des Plantes, General Slade, Mrs. G. Rundle; a very fine lot, and the best twenty-four we have seen as yet this season. Second, Mr. James, of the Rochester Castle, with Rev. J. Dix, Yellow Formosum, Mrs. G. Rundle, Lady Harding, Pearl, Lady Talfourd, Golden Beverley, Cassandra, Dr. Brock, Prince of Wales, General Slade, White Formosum, White Globe, Jardin des Plantes, Lady Slade, Prince Alfred, Venus, Orange Perfection, Beverley, John Salter, Stellaris globosa, Nil Desperandum, Aurea multiflora, Sam Weller. Third, Mr. Berry, of Roehampton, the best of whose flowers were, Queen of England, White Globe, Prince Alfred, Jardin des Plantes, Her Majesty, Empress of India, Yellow Perfection. *Best 12*, Mr. Berry, with Empress of India, Prince of Wales, Golden Dr. Brock, Jardin des Plantes, Lady Harding, Antonelli, Prince Alfred, Beverley, Yellow Formosum, Queen of England, Nil Desperandum, Lady Slade. Second, Mr. James, with Prince Alfred, White Globe, Golden Beverley, Beverley, Venus, White Formosum, Prince of Wales, Nil Desperandum, Golden Dr. Brock, Lady Harding, Mrs. G. Rundle, Aurea multiflora. Third, Mr. Slade, with Orange Perfection, Prince Alfred, Jardin des Plantes, Golden Beverley, and others. *Best 12, separate competition from the last, and more especially adapted for small growers*: First, Mr. Heard, Nurseryman, of Culford Road, Kingsland, with White Globe, Golden Beverley, Dupont de l'Eure, John Salter, Lady Harding, Rev. J. Dix, Beverley, Sir Stafford Carey, Rifleman, Prince Alfred, Robert James, Jardin des Plantes. Second, Mr. Howe, the indefatigable and genial honorary secretary, and one of the mainstays of this old society; his flowers were, John Salter, Golden Beverley, Dr. Brock, Mrs. Rundle, Prince Alfred, Gloria Mundi, Prince of Wales, White Globe, Lady Harding, Jardin des Plantes. Mr. Drain and Mr. Moxham also competed, and put up good flowers. There were two classes for 6 large flowers, to enable large and small growers to compete separately; in one of these (class 10) Mr. Whetdale took first place with Beauty, Golden Beverley, Prince of Wales, Her Majesty, Pio Nono, and Mrs. George Rundle. Second, Mr. Moxham, with Jardin des Plantes, St. Patrick, Lady Harding, Beverley, Prince Alfred, Golden Beverley. Messrs. Heard, Merry, Hodson, Walker, Snare, and Caudrey, also competed. In the corresponding class, for six large flowers (class 11), Mr. Shield was first with Empress of India, very fine indeed; Prince of Wales, Queen of England, Venus, Formosa, Golden Eagle. Second, Mr. James Crute, of Holloway, with Prince Alfred, fine; Golden Beverley, Rev. J. Dix, Beverley, White Formosa, Lady Harding. Third, Mr. Smith, of Haggerstone, who had a fine Mr. Brunles. Fourth, Mr. Heard, of Upper Clapton. *12 Anemone flowers, large*: First, Mr. James, with Madame Goderau, Margaret d'Anjou, Fleur de Marie, St. Margaret, Prince of Anemones, Gluck, Queen of Anemones, George Sand. Second, Mr. Howe, with Lady Margaret, Gluck, George Sand, Queen Margaret, Prince of Anemones. Third, Mr. Snare. *36 Anemone Pompons, in twelve varieties*: First, Mr. James, with beautiful bunches of Antonius, Perle, Florence Nightingale, Madame Sentir, Regulus, Firefly, Mr. Astie, Queen of Anemones, Roso Margaret, Madamo Montels, Marie Stuart. Second, Mr. Howe, with Regulus, Mr. Astie, Toinette, Margaret de Wildeman, Perle, Madame Chalonge, Antonius, Sidonie, Madame Montels, President Morel, Mrs. Wyness, Firefly.

NEW VARIETIES.—Mr. Wyness, gardener to Her Majesty at Buckingham Palace, had a first-class certificate for a beautiful flower called *Princess Beatrice*. Mr. A. Forsyth, of Brunswick Nursery, Stoke Newington, obtained a first-class certificate for a fine flower called *Mrs. Sharpe*. Mr. Slade took first place for the best six new varieties of 1866-67, with Lady Talfourd, Mrs. G. Rundle, Gloria Mundi, Hereward, Golden Beverley, John Salter, all fine flowers. Messrs. E. G. Henderson and Son, Wellington Nursery, St. John's Wood, presented a beautiful collection of cut flowers, for which a special certificate of merit was awarded; amongst them were two new Japanese varieties of splendid character. *Cresse de Beauregard* is of immense size,—say very nearly as large as the crown of a hat,—the petals (florets) spread out from the disk like finely-cut strips of soft silk, their colour being a beautiful shade of rosy-pink, the colour of the disk yellow. *Madame Godillot* is large, but not in that respect equal to the last; the rays are wiry or thread-like and much curled, a sort of mad-looking flower, of an intense orange-red colour; the centre yellow. All proper florists are horrified at the sight of such things as these, but they will please people who like a gay conservatory without regard to the technicalities of floriculture, and we strongly recommend them for their intrinsic beauty.

MISCELLANEOUS.—Mr. Ware, of the Hale-Farm Nurseries, Tottenham, enriched the exhibition with a set of three large neatly-made baskets filled with choice hardy plants, consisting chiefly of Sedums and Sempervivums grouped in masses as for bedding effects. Amongst them the most conspicuous for colour were Sedum dasyphyllum, Sedum glaucum, Sempervivum californicum, Sempervivum tectorum; this, though common, is very effec-

tive at this time of year, owing to the fine brownish purple colour it acquires. Mr. George had a certificate of honour for a beautifully furnished épergne for the dinner table. Mr. Shirley Hibberd contributed a mixture of plants for filling up, also a collection of specimens of Ivies, about fifty in number, and a collection of examples of variegated Kale, some of which were finely cut and richly coloured. These and the ivies were principally shown to indicate their suitability for the decoration of flower beds in winter.

NORTH-WESTERN AMATEURS'.

This Society restricts the competition for its prizes to amateur cultivators only, and its exhibitions have always been supported with spirit. On the present occasion, though the show was opened on the 13th, there were many beautiful collections of both plants and flowers, and the effect produced was highly gratifying.

PLANTS.—*First*, 12, Mr. Dolamore—the most attractive plants in this group were Prince of Wales and Hereward; second, Mr. Cox, who had fine examples of Prince of Wales, Gloria Mundi, and Beverley. *First*, 6, Mr. Morris, who had beautiful examples of Prince Alfred, Beverley, and White Globe—this being a very fine group; second, Mr. Bamlet, who had Prince of Wales and Beverley, fine; third, Mr. Cox, who lighted up a good group with a fine Antonelli; fourth, Mr. Spring. 18 *miscellaneous*: first, Mr. Bamlet, with a very pretty lot, just such as should be found at this time of year in every conservatory. The Cedo Nulli series were conspicuous in this group for their sparkle and freshness. *Second*, 18, Mr. Cox. *Three specimens*: first, Mr. Dolamore, Beverley and Gloria Mundi particularly fine; second, Mr. Norris, who had a fine Golden Dr. Brock; third, Mr. Cox, who had a fine Little Harry.

Plants, comprising incurved, reflexed, anemones, and pompons—12: first, Mr. Morris, with a splendid group, in which Golden Cedo Nulli made a conspicuous figure; second, Mr. Wilson, whose best plant was Lady Harding; third, Mr. Hartell. 6 *pompons*: first, Mr. Jennings, a beautiful group, rich in colour; second, Mr. Cox; third, Mr. Morris. 3 *pompons*: first, Mr. Wilson with Bob, Cedo Nulli, and Miss Julia; second, Mr. Cox, with white, yellow, and lilac Cedo; third, Mr. Paine. 1 *large flowering plant in any sized pot*: first, Mr. Pain, with Little Harry, one of the very best for the purpose, and admirably done; second, Mr. Isaacs, with Vesta, plenty of bloom, and well grown, but training rather defective; third, Mr. Dolamore; fourth, Mr. Parkinson. 1 *specimen pompon* in any sized pot: first, Mr. Cox, with Cedo Nulli, nicely finished; second, Mr. Isaacs, with Madame Marthe; third, Mr. Burnham.

CUT FLOWERS.—*Best* 12: Mr. Dolamore, who had Gloria Mundi and Lady Harding extra fine; second, Mr. Wilson, who had Rev. J. Dix and Prince Alfred good. 6 *large anemone flowers*: first, Mr. Dolamore. 12 *mixed large flowers*: first, Mr. Dolamore, with a fine lot, comprising Beverley, Princess of Wales, Nil Desperandum, and Golden Beverley; second, Mr. C. E. Do amore, who had fine examples of Empress of India and little Harry; third, Mr. Wilson. 6 *incurved*: first, Mr. Bamlet. 6 *large flowers*, grown in the open ground without glass: first, Mr. Bamlet; second, Mr. Isaacs. 18 *large flowers*, three in a bunch, with foliage, to be shown in 48-sized pots: first, Mr. Smith, who had Vesta and Beverley fine; second, Mr. D. Dolamore, who had Sylvia, a fine flower, White Globe, and Venus. 18 *pompons*, three in a bunch, with foliage, shown on a board: first, Mr. D. Dolamore, who had Firefly and Florence Nightingale fine; second, Mr. Bamlet, who had Madame Marthe and Duruffet fine. *Bouquet of Chrysanthemums*: first, Mr. Smith; second, Mr. Cox. An extra prize was awarded to Mr. Dolamore for a fine plant of Golden Beverley. The plants, generally speaking, were good; the cut flowers a shade less meritorious.

BRIXTON HILL.

The exhibition by this society, at the Christ Church School-rooms, rather disappointed us in the quality of the Chrysanthemums, but in its entirety this completely eclipses all other metropolitan exhibitions at this time of year, the show of fruit and fine-foliage plants being rich and profuse, and most tastefully managed. We remember when Mr. Cannell, now of the Fuchsia Nursery, Woolwich, laboured in establishing this society, making it a primary feature of its foundation that every available subject of the season should be admitted and encouraged, and the result abundantly justifies the labour expended, and the broad basis selected for the work. Having attended many of the exhibitions at Brixton Hill, we have great pleasure in recording that on the present occasion, though the principal subject of display, owing to an untoward season, was scarcely so good as in former years, the exhibition, nevertheless, was well worthy of the efforts that had been bestowed upon it, and afforded delight and satisfaction to all concerned.

PLANTS.—*Six Large*: 1st, Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, with splendid plants of Vesta, Chevalier Domage, Christine, Golden Christine, White Christine, Abbé Passaglia. This group made a fine picture, and well sustained Mr. Weston's well-earned fame as a grower of specimen plants; he is as perfect a master of the chrysanthemum as of the fuchsia. 2nd, Mr. Howes, gardener to — Butler, Esq., Tulse Hill, with Attraction, Golden Hermine, Alma, Abbé Passaglia, Annie Salter, Florence Nightingale; a fine lot. 3rd, Mr. Smith, gardener to S. Oxley, Esq., with well-trained but rather backward plants, the best of which were Chevalier Domage and Vesta. *Six Pompons*: 1st, Mr. Weston, with well-trained plants of Golden, Lilac, and White Cedo Nulli, Andromeda, Lizzie Holmes, Hélène. *Six Pyramid Pompons*: 1st, Mr. Weston, with beautiful specimens of Canrobert, Andromeda, Miss Julia, Adonis, Golden and White Cedo Nulli. 2nd, Mr. Wells, gardener to J. F. Bennett, Esq., Tulse Hill, with Trophée, Andromeda, and others. 3rd, Mr. Crisp. *Three Chrysanthemums*: 1st, Mr. Alunn, gardener to — Treadwell, Esq., with fine examples of Jardin des Plantes, Golden Christine, and White Globe. 2nd, Mr. H. Battery, gardener to A. Houlder, Esq., Clapham Park, with Florence Nightingale, Christine, and Coronet. 3rd, Mr. Smith, who had a fine Cardinal Wiseman. *Three Pompons*: 1st, Mr. Glover, gardener to — Vickers, Esq., Streatham Common, with White, Lilac, and Golden Cedos, beautifully trained and flowered. 2nd, Mr. Howes, gardener to Mrs. Butler, Tulse Hill, with Golden and Lilac Cedo, and Andromeda; small plants, smothered with flowers. 3rd, Mr. Battery, who had good examples of Golden Cedo and Adonis. *Three Pyramid Pompons*: 1st, Mr. Alunn, who had in his group a fine Duruffet, showing the high qualities of this favourite variety when well done. *Best single specimens, large*: 1st, Mr. Weston, with Abbé Passaglia.

CUT FLOWERS.—24 *large incurved*: 1st, Mr. Salman, gardener to J. Raycus, Esq., with a splendid lot, comprising Prince Alfred, Golden Beverley, Lady Slade, Mrs. Cunningham, Nil Desperandum, Lucidum, Alarm, Goliath,

Iona, Lady St. Clair, Chernb, Princess Louise of Hesse, Princess of Wales, Robert James, Mrs. E. Miles, White Globe, Jardin des Plantes, Nonpareil, Prince of Wales, Beverley, St. Patrick, Queen of Englaad, John Salter, Lady Harding. 2nd, Mr. Whibley, gardener to Dr. Hood, of Croydon, with Little Harry, Admiration, Prince Alfred, Venus, Little Pet, Sam Slick, Beverley, Golden Ball. 3rd Mr. Webb, who had a nice lot, comprising Rifleman, Golden Beverley, Bella Donna, &c. 12 *large incurved*: 1st, Mr. Howes, with splendid examples of Jardin des Plantes, White Queen (Empress of India), Queen of England, Empress Eugenie, Virgin Queen, Mr. Brunles, Lady Harding, St. Patrick, Maréchal Duroc, Beverley, Prince of Wales, Dupont de l'Euro. 2nd, Mr. Salmon, with Priace of Wales, Lady Harding, Princess of Wales, and others. Equal 2nd, Mr. Webb, with Jardin des Plantes, Beverley, Boadicea, &c. *Six large incurved*: 1st, Mr. Howes, with White Globe, Mr. Brunles, Beverley, Venus, Jardin des Plantes, Abbé Passaglia. 2nd, Mr. Wells, with a fine Yellow Formosum, Themis, Cassandra, &c.

MISCELLANEOUS.—Mr. Wells and Mr. Spooner put up the best groups of stove and greenhouse plants in flower, comprising beautiful specimens of Erica hymalis, E. gracilis, Oncidium incurvum, Cypripedium insigne, Epacris Lowii, &c. In the class for fine-foliage plants, 1st, Mr. Tilce, gardener to J. Stutter, Esq., with a fine variegated pine, Alocasia Lowii, A. metallica, Cissus discolor, &c. 2nd, Mr. Salmon, with Maranta zebra, Alocasia zebraia, Maranta Portea, &c. The class for the best ornamental basket of plants was admirably filled—1st, Mr. Whibley; 2nd, Mr. Livermore; 3rd, Mr. Alunn. Various decorative plants and fruits were shown by Messrs. Livermore, Brasher, Glover, Carter, Faulkner, and others; amongst them we noticed good samples of Chinese yam, and well-ripened Sir Harry strawberries.

EAST TOWER HAMLETS.

The exhibition of this society, at the Edinburgh Castle, Rhodeswell Road, Stepney, was well worthy of the favour shown it by the public, for the attendance was highly satisfactory. The grouping of the plants was accomplished with taste and skill, and the general effect was improved by the contributions of Mr. Prestoe, of Victoria Park, who sent a fine lot of fine-foliaged plants.

PLANTS.—*Six pompons*: 1st, Mr. S. La Roche, with General Canrobert, Lilac, White and Golden Cedos, Miss Julia, Rose Trevenna; a fine lot, well trained, and with plenty of flowers. *Three plants, large flowers*: 1st, Mr. S. La Roche, with Annie Salter, Beauté du Nord, and Gloria Mundi, fine; 2nd, Mr. Baynton, with Golden Beverley, Princess Louise of Hesse, and Gloria Mundi. *Three untrained pompons*: 1st, Mr. Long, with Bcroll, Cedo Nulli, and Mr. Astie; 2nd, Mr. La Roche. *Four standard pompons*: 1st, Eickhoff, with the best standards in the show; the varieties were Antonius, Lilac Cedo, Aurora Borealis, Miss Nightingale. *Miscellaneous collection*: 1st, Mr. Eickhoff; 2nd, Mr. Pierce.

CUT FLOWERS.—24 *large*: 1st, Mr. W. Long, with a very fine lot, comprising Oliver Cromwell, Beverley, Nil Desperandum, Prince Alfred, White Globe, Anaxo, Vesta, Boadicea, Cassandra, Princess Marie, Novelty, General Bainbrigg, and others; 2nd, Mr. W. Eickhoff, with Little Harry, St. Patrick, General Slade, Nil Desperandum, Antonelli, and others, a rather poor lot. 12 *large*, a silver cup for the 1st, which was awarded to Mr. R. Askint, who showed a fine dozen of flowers comprising Cassandra, Prince Alfred, Beverley, Golden Beverley, White Globe, Rev. J. Dix, Cherub, Aregina, Nil Desperandum; 2nd, Mr. S. La Roche, with Gloria Mundi, Anaxo, Cassandra, Golden Beverley, Beverley, Prince of Wales, Abbé Passaglia, Princess Marie, a good lot; 3rd, Mr. W. Long, with Prince Alfred, Anaxo, Beverley, Gloria Mundi, White Globe, &c. 6 *large*: 1st, Mr. W. Long for a pretty lot, comprising Prince Alfred, Beverley, Princess Marie, Rifleman, Princess Louise of Hesse; 2nd, Mr. Eickhoff, with St. Patrick, Beverley, Nil Desperandum, Princess Louise of Hesse, Anaxo, Princess Marie; 3rd, Mr. Pilgrim, with Boadicea, Oliver Cromwell, Princess Louis of Hesse, Mrs. Haliburton, Princess Marie, Nil Desperandum. 18 *anemone pompons*: 1st, Mr. W. Eickhoff, with Antonius, Mrs. Wyness, Firefly, Madame Cha'onge, Miss Nightingale, Sidonie, Astrea, Margaradetta, a pretty lot; 2nd, Mr. S. La Roche, with Antonius, Perle, Calliope, Regulus, and others; 3rd, Mr. W. Long, with Perle, Regulus, Mr. Astie, Mrs. Wyness, Astrea, &c. 4th, Mr. Warren, with Mr. Astie, Perle, Calliope, Mrs. Wyness, Regulus, Astrea.

INSTRUCTIONS FOR THE CULTURE OF THE GLADIOLI.

The culture of this tribe, descended from *G. Gandavensis*, which itself has its origin from a hardy species, the *G. Psittacinus*, does not require any particular care. It will suffice to plant the bulbs in good ordinary garden soil, as much as possible well prepared previously to the planting season. They dislike a stiff compact soil, and succeed generally well in good friable sandy loam. They ought not to be planted in the same place for several consecutive years, and it must not be before the second or third year that they are brought back to the same spot.

Dry warm soil requires as a manure cow-dung, whilst in strong damp land horse-manure or road-scrappings are preferable. The proper season for planting is from the beginning of March till June, from fortnight to fortnight. In this manner a succession of bloom will be ensured from July till November. The late planted bulbs, however, will not ripen enough to be depended upon with safety for a following plantation. The largest bulbs generally flower first, but rarely produce the finest spikes. When planted simultaneously, large, medium, and small bulbs, there will be a good succession. If flowers are wanted as early as June, some bulbs can be planted in 6-inch pots in January, which are either placed in a cold frame or sunk in the soil under a south wall, and there covered with dry leaves or litter until the frost is over. Large bulbs must be planted 4 inches and small ones 2 inches deep. In case of drought, copious waterings are recommended.

As soon in the autumn as the leaves begin to dry or turn yellow, generally at the end of October, the bulbs may be considered sufficiently ripe to be taken up, and after having been dried, are to be stored in shallow boxes in a room where no frost is to be feared.

When the spikes begin to bloom, they may be cut and placed in flower vases, where they will continue to develop themselves, and thus make the finest bouquets imaginable, if associated with some verdure, such as Tamarix, Asparagus grass, or Arundo donax.—EUGENE VERDIER, *Fils aîné, Gare d'Ivry, Paris.*

BEDDERS.—No. II.

Unfortunately, when I prepared my former paper on this subject it was hurriedly written, and I had not sufficient time to refer to the contributions of your able correspondent, Mr. McElroy, which appeared in the Magazine of 21st and 28th September last, under the heading of "Ornamental-leaved Plants for Flower Garden." This is to be regretted, inasmuch as I should perhaps have merely referred to his remarks on several of the plants named, and not have troubled your readers with a repetition of what had been previously written by this experienced and able writer, although it may perhaps serve to do good, as my experience and opinion of the merits of the plants is with few exceptions much the same as that of Mr. McElroy. I will, however, briefly refer to a few of his remarks, more with a view to elicit the opinions of other amateur cultivators than for any other purpose. The *Iresine Herbstii* is so well spoken of by your correspondent, that I should be glad to hear from him the "secret" of his success. Is it that the soil of his garden is of a rich, loamy, moist nature, and so situated that the plants have been partially shaded? Its compact habit is certainly a great recommendation, and it is, moreover, easily kept and propagated; but the chief objection to its use is its wretched appearance at a time when everything else is at its best. And I believe that in nine cases out of ten amateurs by whom it has not yet been tried would be much disappointed with the result.

Centaurea gymnocarpa.—This and *candidissima* are both extremely useful and fine as bedding plants, and for the decoration of the conservatory; the former in particular is very striking during the winter months, mixed with other plants, and has the advantage of being more easily propagated, and is in my opinion much the prettier of the two, although both are undoubtedly very beautiful. I have used it as an edging to a large circular bed of *Coleus Verschaffeltii* this summer with the greatest possible success. The *Coleus* when well "done" is unsurpassed as a "foliage bedder." The plants should be struck early in the spring (in moist heat), potted off, and when the roots have taken hold of the soil the tops must be taken off. This will cause them to break and make nice bushy plants, which must be very carefully hardened off, and transferred to the flower garden the first or second week in June: not a plant here and there, but plenty of them, so that the ground may be well covered at once; this, and well trenching and manuring the soil prior to planting, I believe to be the secret of success. The *Centaurea* formed a most charming edging, and served as a protection to the roots of the plants; and by keeping the whole of the plants of the *Coleus* the same height, by occasionally pinching unruly shoots, it was truly beautiful and the colouring perfect. I consider it a mistake to recommend *Coleus marmorata* as a "bedder;" it is by no means so suitable for that purpose as *C. Verschaffeltii*; neither do I believe either *C. Gibsonii* or *C. Veitchii* will be nearly so effective. The latter of these is extremely good and pretty as a pot-plant for conservatory decoration, and is well worth cultivating.

Centaurea candidissima "*compacta*" (syn. *ragusina compacta*).—A great improvement on the former variety, but its price, consequent on its rarity, is much too high at present for it to be extensively used.

Poa trivialis argentea elegans.—I quite agree with Mr. McElroy as to the merits of this plant; it is without question remarkably effective in vases and suspended baskets in the winter and spring months, but quite useless as a bedder. I gave it a fair trial, and treated it well; but it had to be removed and replaced with my favourite *Dactylis glomerata*. I was much struck with its elegant appearance when visiting Messrs. Henderson's nursery, in the spring, and it is well worth growing in the manner described, or in pots, to be used as an edging for the front of a greenhouse stage; in this way it is grand.

Stachys lanata.—Not only is this quite hardy, but the difficulty is to kill it by almost any treatment. My stock was taken up just before the severe frost of last winter set in, and was by accident left exposed in a basket more than a fortnight; still it did not appear to have suffered much. It is a good poor man's bedder, looks well the whole year round, and if kept carefully and constantly pinched, is by no means a bad border or edging plant.

Balm, Golden Variegated.—In spring in a rockery it is exquisitely beautiful; but surely, Mr. McElroy, you do not recommend it as a bedder? Why, for nearly the whole of the summer it is in colour a miserable patchy green, with scarcely a mark of variegation showing. The "variegated mint," on the other hand, I have frequently seen do well, and retain its variegation perfectly; but even that at its best is not a desirable bedder; it is far too weedy, and never, in my

humble opinion, looks so well as many other of the numerous plants now so extensively used for edging.

Alternanthera, and their varieties.—I have tried *spatulata* out of doors on a small scale this year. It has done moderately well, sufficiently so to warrant a further trial; but I fear neither of them will make good bedders. Grown in pans for the greenhouse they are grand. I exhibited them at the last Taunton show, when they were very much admired. In this way they cannot fail to please.

Cerastium Biebersteinii.—Mr. McElroy has very much astonished me with his remarks on this plant. My experience differs entirely with his. I have tried it over and over again, always with the same result; and, strange enough, when visiting gardens where this class of plants is extensively used, I have heard but one opinion expressed, and that the same as my own,—"that *tomentosum* is by far the most effective." I consider *Biebersteinii* as only fit for the muck-heap; it is certainly not, for effectiveness, and general usefulness, to be named in the same day with its old successful rival, *tomentosum*. I find the latter should be replanted every third year, early in the spring; few plants look better as a broad edging to beds on a lawn. It must be frequently pressed by the hand into shape, and merely the straggling points kept cut. I have seen it in great perfection in the gardens at Kew and the Crystal Palace.

Fuchsia Golden Fleecy (E. G. H. & Son).—When I first met with this at the Exhibition of Tricolors at the R. H. S. Gardens in September last, I must confess I had my misgivings as to its being useful as a bedder, although in habit and colour it seemed all that could be desired. My doubts, however, on visiting the nursery in which the plants were growing, in a bed in the open ground, were quickly dispelled; for I at once saw that it was a real gem, and could not fail to bear out all that had been said of it. I hope to be able to give it a trial on a small scale next year, and strongly recommend others to do likewise.

The Laurels, Taunton.

J. B. SAUNDERS.

CULTURE OF THE TURBAN RANUNCULUS.

We may visit many gardens in the present day, in the spring of the year, without having the gratification of witnessing a bed of Turban Ranunculuses in bloom. But we can remember the period when scarcely a garden in which flowers were grown but would include amongst the early-flowering plants a bed of this then popular florist's flower, embracing all the varieties of Turbans, viz., the scarlet, yellow, and black. I do not think I exaggerate in saying that, among the many roots which are grown in masses, there are few when in bloom that surpass, for dazzling effect, the scarlet Turban Ranunculus. Their omission, then, from the list of roots which are planted for late spring decoration can, I think, be traced to no other cause than that they require extra attention in their treatment, in order to insure the certainty of their blooming in perfection. I introduce these remarks specially at this season, because most of us now are allotting to each bed the several kinds of roots and bulbs that we are about to plant for early and late spring flowering. Although the operation of planting the Ranunculus may be deferred to the latter part of January, or beginning of February, nevertheless it should not be later than the above dates. However, we had better at once prepare the beds for the reception of the roots, so as to be able to avail ourselves in the season of planting of the first favourable weather that may occur.

No root profits more by a change of soil than does the Ranunculus; so that in annually preparing your bed you should at least add about twelve inches in depth of fresh soil. But previous to contributing the same, let that which remains after the removal of the old soil be forked up to at least an additional depth of twelve inches, mixing with the same some good rotten manure. I prefer cow-manure free from any litter, if it is to be had. My reasons for giving preference to this is that its properties are moist and cooling, and also that it retains these qualities longer than most other manures, especially during hot and dry weather. Manure should also be mixed with the fresh soil. Some persons pour it in a soluble form on the surface, believing that the force of the rain will cause its nourishment to penetrate the soil. But it is far better to use solid manure, as this not only nourishes, but improves the texture of the soil. The kind of earth in which these roots thrive best is a good yellow loam; if that is not procurable, choose the top spit of a pasture. If the latter has been stored away for some time so much the better, as then its fibrous portions will readily separate with the aid of a fork. Although the Ranunculus is partial to plenty of moisture at its roots during hot weather, yet it is very impatient of anything like stagnant damp, which soon causes the foliage to turn yellow,

and thus checks their blooming and spoils their beauty. To avoid this, always provide sufficient drainage at the bottom of the bed.

Previous to planting, the surface of the bed should differ from the generality of flower-beds, by its being formed on a perfect level, rather below than above the surrounding surface, which will enable it to retain the water regularly over the whole that you may supply the roots with.

The distance in planting from root to root should be about four inches. I generally plant with a blunt-pointed dibber, making the holes about one or one and a half inches in depth. After I have dropped the root in, I fill it up with silver-sand: this assists to preserve the roots from worms and similar vermin. Those who are famous for the successful culture of choice varieties are very exact as to the depth of soil which should cover the crowns; as they assert, that should the earth which covers them exceed one inch and a half, the consequences would be that other roots would be produced above the crown of the original, and thus check their blooming, and in many instances the whole would dwindle to naught. It is a very rare occurrence for such newly-formed roots to survive their parents, so, by way of insuring the correct depth, many persons plant in drills, especially where the surface is a perfect level.

When the foliage is well above the ground, with your hand press the earth gently but firmly round the base of the plant. This operation will exclude the air from coming in contact with the root, and so check a too rapid evaporation of the moisture contained in the soil.

They should not be allowed, particularly during the growing or blooming season, to suffer in the least from drought. When watering them, do not dash it over the foliage, but pour it on the surface, so that it will gently distribute itself in streams over the whole of the bed. When they are in flower, endeavour to prolong their season, by affording them a slight shading for a few hours during the hottest part of the day; do not let it remain beyond the time it is actually required, or it will weaken the flower-stalks. Growers of choice varieties always provide themselves with permanent means for shading, but anything temporary will suffice, especially where there are a number of other kinds of beds surrounding them containing flowers: in such a case anything that would prove a disfigurement should be avoided. When they are past flowering, withhold the supply of water, and allow their foliage gradually to decay. After they are taken up from the ground, let them be placed in an airy room or loft to dry, then on some rainy day you can cleanse them of the earth, and store them away either in bags or drawers. They must not, after being dug up from the ground, be too long a time exposed to the influence of the atmosphere, or they will shrivel; but I should advise the purchase of a few imported roots annually, so as to fill up all blanks caused by the decline of the vigour of the stock.

JNO. F. McELROY.

THE FALL OF THE LEAF.—Plants, too, have their idiosyncrasies as well as other creatures. There are some which will develop their leaves a fortnight or so earlier than their brothers of the same species, others that will retain their foliage long after it has fallen from other plants of the same specific form. This did not escape the notice of the old Greek naturalists, for Theophrastus, in his work *De Plantis*, mentions a plane-tree in Crete which never shed its leaves, and he adds, that that was the identical tree beneath whose shade Jupiter carried on his flirtation with Europa. Be that as it may, it is quite certain that, apart from individual peculiarities, such as we have just mentioned, plants of the same species will shed their leaves sooner or later according to the locality in which they grow. In the Canary Islands the vine only sheds its foliage very gradually, so that new leaves often appear before all the old ones are thrown off. The cherry-tree in Ceylon, and the peach in Brazil, are said to become almost completely evergreen. On the other hand, in colder latitudes than ours the leaves fall earlier, in consonance with the earlier advent of winter. In the tropics, although there is in general not so well-marked a period of defoliation, yet the dry season seems to act in a similar way to the winter season here. Travellers tell us that there is scarcely a month in the year in which young shoots and leaves may not be seen on the trees, so that the formation of the young leaves, as well as the fall of the old ones, is spread over the whole year, as it were, and is not so much confined to particular periods as in temperate latitudes. On the whole, then, of all the assigned causes for the fall of the leaf, this last, dependent on an alteration, or rather on a new growth in the leaf itself, is the most important, and probably the only one of itself sufficient to produce the result. It remains now to be seen whether this separating layer is of universal formation in the case of deciduous leaves. For many reasons we are inclined to think that it is not formed when leaves fall off prematurely, as they do from drought or injury. But supposing it to be of general occurrence under what we may term ordinary circumstances, it still remains to be ascertained what are the precise conditions inducing the formation of this peculiar layer of tissue. It is easy enough to say that the layer in question is formed owing to the disproportionate growth of the tissues, those of the stem being active, while those of the leaf are obstructed and comparatively inert. This may be so, but there is no direct evidence on the point as yet. We admit the facts, but the precise relation of those facts one to another is not yet fully made out; till this is done, the explanation of the fall of the leaf cannot be considered as fully satisfactory.—DR. MASTERS, in *Popular Science Review*, October.

THE BAMBOOS, ETC., AT FOATY, COUNTY CORK.

Foaty, the fine residence of Mr. Smith Barry, M.P., is one of the most extensive and horticulturally interesting in the south of Ireland. It comprises nearly eight hundred statute acres; in fact, the entire area of Foaty island, which is somewhat over a mile and a half in length by three-quarters of a mile in breadth. Foaty is situated in one of the deep receding bays or reaches of that broadly spreading portion of the beautiful estuary of the Loo known as Lough Mahon. Where the inlets are narrowest the demesne is connected with the mainland on one side and the Great Island on the other by bridges, near to which are situated the unusually spacious and imposing gate entrances, by which access is had to the main approaches or carriage-ways leading to the mansion. The latter is a spacious and commodious building, without any ornate or architectural pretensions. Its worthiest ornaments, and in truth most imposing ones, are the truly magnificent evergreen oaks by which it is flanked on either side of the broad carriage-ring in front. The demesne presents but little variety of surface, and the situation of the house is rather low. The gardens, which are in close proximity to the house, are very extensive. By fine cross walls they are divided into four compartments. In one division are some small forcing houses, a melon yard, and flower ground; the others comprise nuttery, orchard, and kitchen gardens. The whole kept in excellent condition. The extent of glass is at present small, and quite out of proportion with the place, a defect which we understand is likely soon to be remedied. Besides the frames and pits, the only glazed structure in the division of the garden above alluded to, are two very small lean-to houses, one used as a vinery, the other a plant-stove.

Outside the gardens, and near the drawing-room front of the house, there is a short range, also a lean-to. It is in two compartments, one a plant-house or conservatory, the other a vinery. On occasion of our visit the condition of this last was more than ordinarily interesting, as affording an example of a skilful operation carefully and scientifically carried out. The gardener, Mr. Osborne, being desirous to overhaul the vine border and re-make it *de novo*, set to work, and notwithstanding that the vines were carrying a crop, and in full foliage, did the work well and effectually, without injury, or the latter even flagging. When we were at Foaty the roots, divested entirely of soil, were comfortably wrapped up in bass mats, the border meanwhile being drained, concreted, a good depth of rubble placed over the concrete, and on this a tough sod, upper surface downwards, and quite ready to receive the prepared fresh soil and replant the vines. Time was thus gained, and the vines are now making abundance of young roots, and will be well established in the fresh soil before winter fully sets in. We are digressing, however, as the object of this notice is not a detailed account of the demesne or gardens of Foaty, but rather of some features peculiar to it, and which are not without interest in connexion with acclimatization, Conifers, and what is called sub-tropical gardening. An islet of bamboos is something to admire and wonder at in these latitudes. At some distance to the left of the mansion, in a secluded spot, surrounded by lofty trees, there is a small sheet of water, containing two islets, and these are nearly altogether monopolized by tufts of graceful bamboo, growing in the greatest luxuriance. Some of these are of deepest green, others very much lighter in colour, and forming a pretty contrast.

The margin of the water is dotted with tufts of New Zealand flax plant (*Phormium tenax*), Pampas grass (*Gynerium*), and the royal fern (*Osmunda*), and these again, with the variegated *Arundo donax*, indicate the course of some streamlets formed for drainage, or to conduct the overflow from the water surrounding the islets. Around are some beautiful specimens of Coniferae, more especially of the gigantic red wood (*Sequoia sempervirens*), nearly sixty feet high; *Taxodium distichum*, *Cupressus funebris*, and *Cryptomeria Lobbi*. As seen at Foaty, this last is about one of the most beautiful of Conifers, the specimens averaging over fifty feet in height and nearly eighty in circumference below, perfectly symmetrical, feathered from the base to the apex, and forming masses of the richest verdure. *Cryptomerias* and *Sequoias* seem to be peculiarly at home here. We also noticed lovely specimens of *Pinus pinsapo*, about thirty feet high. *Abies Smithii* very fine. We only noticed one specimen of *A. nobilis*; it did not seem to be doing particularly well, and had, too, lost its leader. Near it a nice specimen of *A. Webbiana* was ornamented with its striking, upright, dark, richly-coloured cones. Specimens of *Thuopsis borealis* and others were over thirty feet high. Besides the Conifers, many other beautiful specimens dotted over the grounds attracted attention; for example, magnificent specimens of *Ligustrum lucidum*, laden with its thyrses of flowers, fine standard *Magnolias*, *Catalpas*, a grand old specimen of the Cork oak, *Quercus suber*, and the curious *Colletia horrida* could not fail to arrest the visitors' attention. *Eucalypti* were flourishing uninjured, though we have seen them cut off in other parts of the south. *Aster argophyllus* seemed to have suffered, though not killed; for when headed down it again grew vigorously this year. Very old *Yuccas* form a remarkable feature in the grounds, and a small oval bed, planted with American aloes, and bordered with the Chinese coltsfoot (*Farfugium grande*), formed a pleasing combination.

An interesting example of the employment of sub-tropical plants for outdoor decoration here, long before it was thought of at Battersea, presented itself, in the shape of the Fan Palm (*Chamareops lunulata*), planted out for years in the garden. It is now over ten feet high, and as much across. We could have wished this perhaps unique specimen of outdoor Palm culture were standing prominently among the other interesting trees in the grounds, instead of in the retired corner, where the effect is, in a great measure, lost. Alongside, and almost within shade of its fan-like leaves, a specimen of the Coral Tree (*Erythrina cristigalli*), with about ten flowering stems, was opening its brilliant blooms. If time permitted, and the afternoon, which was dropping, had been more favourable, doubtless many other interesting things in the plant way would have cropped up.

Before closing this hurried notice, we will for a moment return to the interesting spot where the Bamboos luxuriate in their little island homes, a spot which is characterized by a peculiar quiet, with a view of suggesting the trial in the same place of two or three plants, which would, probably, succeed equally well, and add a new feature of interest to Foaty. The New Zealand Tree Fern (*Cyathea dealbata*) in the centre of each little islet, and towards the edge the Paper Reed of the ancients (*Papyrus antiquorum*), alternating with the tufts of Bamboo and *Disa grandiflora*, with its rootlets drinking the water, and fringing its margin with its lovely blossoms, would form a rare picture, and be an episode of no ordinary interest in the history of sub-tropical gardening. Is this only a dream? or shall it fall one day to our lot to record the success of the experiment, and the spirit of the kind-hearted and generous young proprietor of Foaty?—*Irish Farmer's Gazette*.

THE PEAR, WITH SOME REMARKS ON ITS CULTIVATION AND MANAGEMENT.

We so seldom see a good collection of well-managed pears in private gardens, that we should be justified in saying that they are neither known nor appreciated as they deserve to be, did our experience, in part, not convince us of the contrary. As a gardener of some years' standing, I have had many opportunities of proving that a dish of fine, ripe, well-grown pears is appreciated by every owner of a garden, but it is so seldom the case in the majority of gardens that a dish of fine pears is to be had, that when I say they are not sufficiently known, the remark will apply with force to a great number of private gardens. Surely it is not as it should be, that a subject so easily cultivated, and so generally admired when well done, should remain almost a stranger in the hands of many cultivators. I may say without fear of contradiction, that no subject belonging to the fruit garden better repays for care and skill than a good collection of pears; but although I have travelled much, I have met with few places in which they can be said to be cultivated with skill and care, though I have seen very many instances where their cultivation has been a slow process of murdering the trees.

As a grower of hardy fruits of some years' experience, I am satisfied that to properly cultivate the pear, with any degree of success, there are a few important principles to be worked out with care and judgment. These principles I intend to explain to the reader in due course, for my object in now writing is to endeavour to assist those readers of the Magazine who may desire information; and I hope, by giving them the benefit of my experience, my efforts to diffuse what I have learnt from practice will be acceptable.

Very much has been said and written upon the subject of dwarfing stocks for pear-trees during the last few years, much that might have been left unsaid and unwritten. Dwarfing stocks for bush or pot trees may be all very well, but if you want to grow pears profitably, you must put them on better legs, or they will be half a lifetime before you see an equivalent return for land and labour employed in their service. Pear-trees in pots, and miniature pear-bushes in the open ground, are to me a sort of playing at gardening, because I have learnt from experience that we must cultivate the pear more liberally, if we desire a liberal return. To do this we must have our pear-trees on the pear-stock, and then with careful management and a suitable soil we may hope to succeed, so that when we go into the garden to gather the fruit, we may require something larger than a dessert basket in which to place our harvest. I advocate, both for trained and large pyramid trees, the pear-stock as being the best known to me, under a great variety of circumstances. But if pyramid trees are required to fruit in a young state, and are not wanted large, then the quince-stock will be the best, as it causes the tree to assume a dwarf bushy character. The consequence of this is that the root action is less vigorous than that of the pear-stock, consequently the tree much sooner arrives at a bearing condition. But then we must remember that the quince-stock requires a much more fertile soil than the other, so that it becomes a question, even for dwarf early-fruited

trees, if it is not best to use the pear-stock on poor, dry, sandy soil. We all know the conditions under which the quince in its natural state thrives best, and I hold that unless we can to a certain extent give it the same conditions we are best without it.

As to soil, there is no kind of fruit-tree which does so well in a strong well-drained loam as the pear. This fact often adapts the pear to some positions where other fruits would not do well, as if the soil is somewhat stiff and cold it will suit such sorts as *Williams's Bon Chrétien*, *Louise Bonne of Jersey*, and the *Crusane*, better than a warmer or drier position. There are few soils but will grow the pear to satisfaction, if the trees can have a first start in some well-rotted dung and fresh maiden loam. Another fact I have learnt from constant observation is, that it is highly necessary to plant early in the autumn, in fact, as soon after the first day in October as rain may occur. Never mind if some of the young shoots are tender and sappy, the move will do them good, by arresting the ascending sap, and the wood will get the riper for the check. Young trees moved thus early will generally start into a vigorous growth about Midsummer the following year, but spring-planted trees frequently make no start at all, and sometimes remain in that state for a couple of years.

Of the forms which the trees should take, there are only two which I can recommend as profitable, the fan shape for walls, and the pyramid form for the open ground. The latter is a very desirable form for every garden, whether large or small, and I cannot advocate its adoption too strongly, for it admits of the tree bearing a good quantity of fruit, and they are at all times highly ornamental. But the management of this form of tree is not generally understood, in fact, it is muddled through in a most unwarrantable manner. The pinching system, so proper to this form of tree when timely and skilfully done, is the rock upon which many have wrecked all their hopes, simply because it has been done in a thoughtless manner, and sometimes without skill or practice to guide the cultivator.

As I have seen so many failures arising from these sources, I have endeavoured in the annexed sketch to point out clearly, as far as it is possible to do so, the points at which the pinching should be done. The cut is intended to represent the side branch of a tree that was pinched back the previous year at figure 12; the shoots shown at figures 3, 4, 5, 6, 7, are the current year's growth, while the marks across them denote the point to which they should be pinched back, not earlier than the second week in July. Figures 8, 9, 10, and

11, represent the spurs from previous years' pinching, but not showing the young growth which they sometimes make, and which must be removed at the same time as the pinching just recommended. As I have just stated, this branch is supposed to be pinched at figure 12; from that point to 13 was the leading shoot of the branch the previous year; but having been headed back, the side shoots, as shown, are the result, with another leader to take its place, to receive precisely the same treatment as the one that preceded it. And now comes the secret of the pinching system. Many go and recklessly pinch every shoot, so that there is no energetic growth in any part of the tree to exhaust the rising sap, which at this season is very active, so that the buds below the point soon push out

into active growth, when under proper management they should be quietly forming themselves into fruit-buds. But when none of the leading shoots are left to use up the ascending sap, the force below is so strong that nearly every new-made bud breaks forth into new leaves and a weakly growth, and then all hope of fruit-buds at those points vanishes. But the case is very different when the leading shoot which starts from figure 12 is left untouched at the time the others are done, as then there is a portion of the branch ready to dispose of the force from below, which it does in a most satisfactory manner, as the buds on the growth headed back will remain dormant, while they have the late summer and autumn months in which to form and mature their fruit-buds. This leading shoot must remain untouched until the end of August, when just its points should be nipped out at figure 1, and in the winter cut down to figure 2, which, with the exception of removing useless spurs or ill-placed branches, is all the pruning they ought to require. None but sluggards and ignorant people will have more than this to do at the winter pruning of pyramid trees. Bear this in mind, brothers of the craft, and all you good readers who are your own gardeners, or else I shall feel compelled to place you in the category of sluggards and otherwise.

Another important feature in the cultivation of pyramid pear-trees is to annually root-prune them. The stronger the soil the more necessary will this be to check a too luxuriant growth. Remove a portion of the soil on two opposite sides of the tree, so as to get below the roots. If a large tree, say ten feet high, tunnel out a space eighteen inches wide beneath the bole of the tree, and sever any roots which you may come in contact with. Those which branch out above more on the surface should be left untouched; they seldom get too strong when the trees stand on cultivated ground. Besides, it is a great mistake of people when they attempt to starve the pear-tree into a fruitful condition; its very nature is to live sumptuously, and if you deprive it of its accustomed food, it will soon resent the injury by producing you no fruit at all.

I may remind the inexperienced reader, too, that the pear does not, and in fact will not thrive profitably if kept to very small dimensions, as it is a subject which to be fruitful requires both size and age. It will not, in fact, settle itself down to be used as a toy, it rather prefers to grow large and imposing; and in such a condition all of us know they are most fruitful and sure. A pyramid tree ten feet high should be considered only a moderate size, and there are not many gardens but would admit of pyramids sixteen feet high. Trees of such a size would be capable of producing upwards of a bushel of fruit.

Here I must close this paper. I thought to have included in this space all that I wished to say; but as only half of the subject has been dealt with, I must leave it for another number.

A COLLECTION OF TWELVE VARIETIES OF PEARS SUITABLE FOR PYRAMIDS.

- Louise Bonne of Jersey*, very productive—October.
- Knight's Monarch*, very fine—December, January.
- Beurré Bosc*, vigorous—October.
- Williams's Bon Chrétien*, sure bearer—September.
- Winter Nelis*—December to February.
- Bergamotte d'Esperen*, fine late pear for a warm spot.
- Beurré Diel*—November.
- Citron des Carmes*, delicious early pear—August.
- Easter Beurré*—March to April.
- Fondante De Charneux*—November.
- Comte de Lamy*—October.
- Ne Plus Meuris*—February, March.

A SOMERSET GARDENER.

THE ALLAMANDA.

The fact that the Allamanda is one of the best and most ornamental stove plants we have, is sufficiently proved by its figuring in nearly every collection of stove and greenhouse plants that we meet with staged for public competition at our leading horticultural shows. In fact, it is the only stove plant of its colour suited for exhibition purposes; for there is nothing else in the stove that can compete with its large handsome blossoms, either in colour or shape. Most of the species are natives of Brazil, and require a stove temperature to grow them properly; the chief requirements for their successful cultivation consists in growing them vigorously after they are started in the spring, and giving them a good rest through the winter. The best method of treating these plants, both in propagation and after culture, is as follows. Suppose we begin with propagating first. For cuttings choose the side shoots after they have grown four or five inches long and have got a little firm, and insert them in any light sandy stuff, with a

layer of sand on the top. The pots are plunged in a brisk bottom-heat, such as is afforded, for instance, by a cucumber or melon bed, and covered with bell-glasses. I find very little difficulty in rooting them with careful attention and watching to prevent their damping off; or, on the other hand, getting too dry. To more effectually guard against the former evil, it is advisable to wipe the glasses occasionally, otherwise the condensed moisture will trickle down the sides of them, and be very injurious to the young tender cuttings. Perhaps some people may imagine this caution unnecessary, but I consider it of quite as much importance as any other operation, and I have seen plenty of cuttings of other plants as well as of this destroyed through nothing else. As soon as the cuttings are nicely rooted, and the pots begin to get full of roots, they should be potted off at once into sixties, and returned to the bottom-heat, and kept rather close until they form new roots and get established in the fresh soil, which should consist of about three parts loam and one of thoroughly rotten leaf-mould, and plenty of sharp sand. For the next shift, which will be into thirty-twos, the soil must be of a rougher texture, and less sand will be required. This shift will, generally speaking, even with a vigorous growth, carry the plants through the first season, for by the time the soil in the thirty-two's is exhausted, it will be time for the plants to be gradually dried off to bring them into rest for the winter. To get a good bottom to the plants, they should be stopped once or twice during the first year's growth, but plenty of time must be allowed from the last stopping for the wood to get well ripened, otherwise they will not break so strong as it is desirable they should the following spring.

Whilst the plants are at rest it is not advisable to keep them as dry as a tuberous-rooted plant—such as a Caladium, for instance. If the atmosphere of the house in which they are wintered is very dry, the wood may shrivel, particularly if it is not matured so well as it ought to be, but they should have no more water than is absolutely necessary to keep the wood plump. But in a house kept to an average of 55°, with the usual amount of atmospheric moisture, it is not at all likely that any water will be required from October until the end of the following February, when the plants will require to be cut back, and be repotted. It is next to impossible for me to lay down any rules as to how the plant should be pruned, beyond saying that the shoots should be cut back to about two eyes each, and the plants kept evenly balanced as regards size and shape. At this potting young plants will require larger pots than those they were grown in the previous season; but plants which have attained to the maximum-sized pot should be carefully taken out, and a portion of the old ball removed to make room for fresh soil, and be repotted in the same size again. As soon as the plants are potted, they should have the trellis for training them upon securely fixed in the pot. It is a much better plan than leaving it until the young shoots are pushing, as there is then no risk of doing mischief in fixing it. If convenient, a nice mild bottom-heat will be of immense assistance in starting them into growth, and the plants should be syringed once or twice a day. Very little water will be required at the roots until they get established in the fresh soil, and the plants make a good growth above. As they progress, every shoot should be trained in its proper place; for if the shoots get hard it will be a difficult matter to bring them into a good shape without snapping them; and an occasional watering with weak manure-water will materially assist them to produce fine large flowers. *A. grandiflora* and *A. Schottii* are two of the best large-flowered kinds; *A. nerifolia* is a more compact-habited plant, with much smaller flowers.

GEORGE GORDON.

It is an undoubted truth that the less one has to do, the less one finds time to do it in.

VENTILATORS.—In most of the existing arrangements for the introduction of fresh air into rooms, the mistake is made of using a few small apertures. Hence, we often find in the houses of persons who pride themselves on the perfect ventilation of their rooms, that these latter have abominable draughts, whose course is defined with the greatest nicety, and which often appear to select one's ears as the most convenient medium of transit. This production of keen sharp draughts has been the opprobrium of nearly all the vaunted ventilators hitherto employed. The method suggested by M. Morin, a French savant, who has paid much attention to such questions as these, obviates in a great measure these defects. His plan is somewhat similar to that recommended by the Commissioners for improving the Sanitary condition of Barracks and Hospitals, so that a description of the latter will represent both. At the level of the ceiling a number of perforated bricks are introduced into the wall, the area of the aperture being in the proportion of 1 square inch to every 60 cubic feet of the capacity of the room. In order to prevent the discomfort which might arise from a down-draught from these openings, a cornice is so arranged as to cover them. The upper side of this cornice is composed of perforated zinc, which thus causes the air to be evenly distributed over the room. The holes are generally from 1/4 to 1/2 in. diameter, and the area of the zinc perforated is to that of the air-spaces as about 6 to 1.—Dr. LAWSON, in *Iopular Science Review*, October.

REPORT ON TRIAL CULTURE OF VARIETIES OF ONIONS AT STOKE NEWINGTON, 1867.

Several points of interest requiring special attention, in connexion with the cultivation of the onion, having lately attracted public attention, it was determined to subject to systematic culture at Stoke Newington the several known varieties, so far as true samples could readily be obtained. Application was made to Messrs. Cutbush and Son, of the Highgate Nurseries, who were the introducers of the now celebrated "Nuneham Park" onion, and they very readily complied, and furnished samples of about thirty varieties, under the several names by which they were known to the trade. When the trial was completed, it was found that the thirty sorts might be reduced in number, some few bearing different names proving to be identical. This is a common occurrence in all extensive and carefully made comparisons of varieties of vegetables and roots that are largely cultivated, and therefore we will not stay to make any remarks upon the fact. The seeds supplied by Messrs. Cutbush and Son were, without exception, good samples, and true to their several names. A few samples were obtained from Messrs. James Carter and Co., and Messrs. Barr and Sugden, after Messrs. Cutbush had supplied all that were desired of them. Owing to the unfavourable weather

naturally at the neck when the bulbs have attained this size, and very soon afterwards the crop is perfectly ripe. Well adapted for frame culture and forcing for salads.

NUNEHAM PARK.—A large, round, much-flattened bulb, of a silvery brownish straw-colour. It was compared with all the other varieties on the ground several times during the season, and in every stage it most nearly resembled the *White Spanish*. It is, however, an improvement on that fine variety, and is usually flatter in form, more completely shrivelled at the neck, and more distinctly marked with small black spots on the under side near the roots. Its value can be best judged, not by comparing picked samples of either variety, but by comparing the whole crop of either from equal extents of ground, when it (the Nuneham Park) will be found to afford nearly double the gross weight of *White Spanish*, and the bulbs will average a larger size, and a more perfect degree of ripeness. This onion is fully worthy of all the praise that has been bestowed upon it, and is undoubtedly the most profitable and handsome variety in cultivation.

WHITE SPANISH.—This is one of the best old varieties known. The *Reading*, *White Portugal*, and the *Oignon d'Espagne*, are either the same, or vary only to the extent that may be looked for when distinct stocks are established in particular localities. In form this is a neat oblate spheroid,

White Globe.

Blood-Red.

James's Keeping.

and bad condition of the ground, it was not until the 16th of April that the seeds were sown. They were then sown in drills, and were afterwards thinned, as became necessary, to allow of the full development of the several sorts. The beds were prepared for them by deep digging, liberal manuring, and a final top-dressing consisting of the finer part of a heap of ashes, the result of a "smother" made of rubbish, tree-prunings, &c. The growth throughout was satisfactory, in some few cases rather too luxuriant; as, for example, in the case of the *Silver Skin* onion, the bulbs of which were far too large for the purpose to which this variety is usually applied, and which is usually and properly grown on poor soil. Nevertheless, a very fine lot of bulbs was harvested in the autumn, and from these a few samples typical in form, but neither the largest nor the smallest in size, were selected to furnish material towards the descriptions which follow, and the cuts with which this report is accompanied.

EARLY NOCERA (Carter and Co.).—A neat early ripening variety, forming a round slightly-flattened bulb, which when ripe is of a bright light brown colour. When the outer skin is removed, the inner coats are of a yellowish or greenish white. It is mild in flavour, moderately sweet, and undoubtedly one of the very best to grow for spring salads or for pickling in autumn. The sample was sown April 20; by the middle of July the bed was paved with bulbs, the largest being an inch in diameter. The grass breaks off

rather stout in the remains of the neck even when perfectly ripe, so as to be well adapted for tying on ropes for the winter, which varieties with less neck are not so well adapted for. The skin is of a silvery brownish straw-colour with sometimes a patch of green showing through. It is mild, sweet, keeps well, and is everywhere esteemed as one of the best.

TRIPOLI, *Oignon pyriforme*.—Large, irregular, more or less angular, base nearly flat, and summit considerably flattened. Skin dull grayish brown occasionally deepening to reddish brown. Flesh white, pungent, and sweet. A heavy bulb, ripening perfectly, but always with a highly tough neck; a good cropper, and keeping well. Our crop was ripe at the end of September.

DEPTFORD, *Brown Spanish* (Barr and Sugden).—Medium size, obtusely conical, flat base, skin reddish brown and glossy. This variety bears a close resemblance to *Danver's Yellow*, but it neither grows so large nor attains to so high a specific gravity. This is a good winter onion, highly pungent in flavour, and keeping well. It is a good cropper, and should be left thick on the ground. Our sample ripened perfectly about the middle of September.

STRASBURGH, *Essex, Flanders*.—Medium size, neat, obtusely conical, nearly flat at the base. Skin grayish brown with a shade of purple showing through from the inner scales. Flesh firm, flavour highly pungent. A good cropper, ripens perfectly, and keeps well.

BLOOD-RED, *Dutch Blood-Red, French Blood-Red, Oignon Rouge foncé*.—

Tripoli.

Silver Skin.

Medium size or smallish, compressed spheroidal, deep purplish red, glassy and handsome. Flesh red, highly pungent, and with a strong taint of the flavour of sulphur. A heavy bulb, a good cropper, first-rate for soups, but quite unfit for any purposes for which "mild" onions are preferred; first-rate for keeping.

JAMES'S LONG KEEPING.—Large, in form varying from almost oval to a quite globular or slightly compressed form; never flat at the base. Skin reddish brown with shades of purple; flesh yellowish, pungent, and emitting a powerful odour. In our soil this variety never finishes well, the largest bulbs being thick-necked, and in form approximating to that of Brown Globe; but the smaller bulbs are hard, neat, perfectly finished at the neck, and keep well, in fact, longer than any other onion. The only way to secure a good crop on our greasy soil is to leave them thick on the ground, like a pavement of pebbles. This is one of the most serviceable varieties known, and in character and appearance approaches nearest to Brown Globe and Blood-Red, of the characters of both of which it partakes.

COVENT GARDEN PICKLING.—A variety of the true Silver Skin, but distinct enough to have a separate place here. Comparing picked bulbs of either, the difference between them is scarcely appreciable; but a comparison of the whole of the crop proves the Covent Garden Pickling to be smaller and better ripened, a very large proportion of the true Silver Skin having been thrown out in the harvesting on account of their unripe condition. The Covent Garden onion may be regarded as an improved Silver Skin, less gross in habit, and ripening early and more completely than the original.

TREBONS.—Large, not flattened, almost oval, the skin light greenish straw-colour; flesh greenish white; mild and sweet. A fine heavy bulb, admirably adapted for late winter use, a good cropper, and ripening perfectly in the middle of September. This is by some regarded as identical with White Spanish, but it is quite distinct. It more nearly resembles White Globe, but differs from that in several particulars.

WHITE LISBON, *Oignon blanc de Florence.*—Large, variable in outline, and

silvery with very faint stripes. Flesh white, tender, mild, and sweet. A rather light bulb, a good cropper, but not keeping well beyond January. S. II.

WAYSIDE DELIGHTS.

Paper read by Mr. W. CHITTY, Florist, of Stamford Hill, at a Meeting of the "Mutual Improvement Society," Wesleyan Chapel, Stoke Newington.

I cannot better introduce the subject of this evening—"Wayside Delights"—than by referring to a little incident that occurred to myself some four or five years since. At that time I was engaged at some distance from home, and one morning, after breakfasting at the little country inn where I domiciled myself while in that neighbourhood, I came up with the old postman who delivered letters in the adjacent village. After the usual salutations and remarks on the weather, &c., the old man said: "Before you came here I used to walk up and down this road without noticing anything, but since reading what you have written about the plants growing by the roadside, I do really find the walk a very interesting one; and in noticing the various plants my walk does not seem so long as it used to be." It gave me very much pleasure to find that I had been the means of adding a new joy to the old man's life. He had lost an arm, in what way I now forget; in other respects he was a very good specimen of a country peasant, courteous in demeanour, hale and vigorous, though between 70 and 80 years of age. Some papers of mine upon the botany of the neighbourhood had been read by him in the columns of the GARDENER'S MAGAZINE, and he had learnt, though very late, that the "waysides" of life are full of objects of interest to the careful observer. It has even happened that plants have derived names from some circumstances which have happened in their neighbourhood; hence we read of the oak beneath which Deborah, Rebekah's nurse, was buried, that it was called *Allonbachuth*, "the oak of weeping" (marginal reading). It is recorded of the botanical traveller, Allan Cunningham, that while pursuing his researches in

Nuneham Park.

White Lisbon.

sometimes almost angular, quite flat at the base, and in outline closely approximating to a triangular form. Skin greenish white, silvery, distinctly marked with brownish longitudinal lines. Mild and sweet, not keeping long, and seldom ripening perfectly at the neck, where it is always slightly moist and supple. A good cropper, and first-rate for summer and autumn use.

EARLY SILVER SKIN, *Oignon blanc hatif.*—Large, the best bulbs measuring three inches in diameter. Round, compressed, scarcely flat at the base, the skin white and silvery with occasional small patches or streaks of whitish green. The flavour of this onion is extremely mild and sweet. It does not keep long, but is excellent for summer and autumn use for dishes in which onions constitute a principal feature. When grown for pickling, poor ground should be chosen, and the seed sown thick, and the whole crop be left to ripen off without thinning. In this trial the soil was far too rich for the production of bulbs suitable for pickling, and a very large proportion were at the end of September in a rank "bull-necked" condition, quite unfit for storing.

WHITE GLOBE.—Large, almost globular, outer skin pale tawny straw-colour, with occasional patches of bright light brown. Flesh sweet and moderately pungent. A good cropper, the principal bulk of the bulb being

Early Nocera.

in vertical measurement allows of the crop being thicker on the ground, increasing thereby the total weight. This variety was ripe on the 4th of August, and all finished off together without having their necks broken. When dry the neck is so shrunk that this variety is not well adapted to put on ropes, as the slightest shock detaches them.

BROWN GLOBE.—Medium size, globular, skin tawny with patches of bright brown. This agrees with White Globe in form and qualities, but does not grow so large, and is of a darker colour.

DANVER'S YELLOW.—Medium size, closely allied to Brown Spanish, but usually with a deeper colour at the base. The bulbs are particularly heavy and solid. The colour is a bright yellowish brown with occasional patches of cinnamon. It is a better cropper, and keeps longer, than Brown Spanish; in every respect first-rate. A picked bulb of 2½ inches in diameter weighed 3 ounces.

GIANT MADEIRA.—Elliptic in form, the root-plate projecting in a degree equal to the neck, the skin pale reddish brown with a faint wash of blue,

Australia he and his companions were at one period suffering from want of water, when they came unexpectedly upon a gushing fountain of excellent quality. The natives who accompanied him were so overjoyed at this discovery, that they gave expression to their gladness by dancing round the spring. It so happened that Cunningham found a shrub in the vicinity which he had not before discovered, and he gave it the name of *Chorozema*, from two Greek words—*choros*, "merry," *zema*, a "dance," merry-dance—in commemoration of their gladness at the unexpected supply of water in the time of their pressing need. The plant was *Chorozema varium*.

But suppose we turn back to the old postman, and walk with him the whole length of his rounds; and, with his newly-awakened interest and new-born relish for plants and flowers, let us peer into the hedge-rows, let us examine the plants in the ditches, and let us note these that spring up and show a bold front to the passer-by from the grass glades of the common-side. The old man's path was one of the richest in subjects of botanical interest that I ever came across. It extended from the town of Leatherhead to the extreme end of the village of Oakshott, bordering upon Oakshott Heath. On either side of the road, in various places, were large patches of *Ononis spinosa*, or rest-harrow, with its beautiful rose-coloured flowers, and well armed with its formidable spines. At one spot I found one plant of a white variety, producing larger flowers than the species. Sweet brier, some fine bushes, very beautiful in their season, when covered with their numerous gauze-like flowers of rich blush. And throughout nearly the whole distance the hedges were, in their season, festooned with rich masses of the *Rosa canina*, dog-rose; the common but graceful bryony luxuriated at many points, producing its glowing scarlet berries in profusion for the decoration of the roadsides during early and mid-autumn; in the season, *Arum maculatum*—or lords and ladies, as they are popularly called—had possession of the banks on both sides throughout nearly the whole length of the postman's route. Bluebells, primroses, foxgloves, furze-bushes, the yellow hroom, blackberries, the lovely bugle-plant, *Ajuga reptans*, the wayside convolvulus, *Convolvulus arvensis*, several beautiful hawkweeds, all in their season, contributed to the interest and pleasure of the passenger. I must not forget the beautiful *Bartsia odontites*, a charming plant, growing from 6 to 12 inches in height, the terminal shoot and the tip of every side-shoot crowned with whorls of flowers of a most lovely rose-colour; and what adds to the beauty of this plant is, that the bracts, or the scale-like appendages that enclose the flowers before their development, are tinged very deeply with the same lovely hue. Always in the neighbourhood of *Bartsia*, the last named plant, and in close association with it, is the delightful little eye-bright, *Euphrasia officinalis*. Wherever I have been hitherto I have always found these two plants associated, excepting in one case at Ewell, where I found *Bartsia* growing alone. Here, between Leatherhead and Oakshott, there are large patches of *Euphrasia*, forming quite a carpet on that part of the common near to "Prince's Cover." The great ragwort, *Senecio Jacobaea*, is very fine in the dampest parts of the locality, producing immense corymbs of its rich yellow blossoms almost into the winter; moneywort, *Lysimachia nummularia*, covers with a rich carpet of green and yellow some very damp spots. One of the most beautiful of English plants, *Erythraea centaurium*, or the common centaur, is very fine in some spots, producing panicles of its deep rose-coloured flowers

in great profusion. The harebell, *Campanula rotundifolia*, is very beautiful in some spots. Perhaps no flower presents a more enchanting aspect than the ladies' bed-straw, *Galium cruciatum*; fine patches of this glorious plant, throwing out immense thyrses of its soft yellow flowers, support themselves by the low bushes on various parts of the common, while the diminutive *Galium pusillum* covers with immense patches of the purest white many places on either side of the road. The hatcher's broom, *Ruscus aculeatus*, is to be found in large patches at the foot of many of the large oaks. The only plant I ever saw of *Epipactis latifolia*, a somewhat rare British orchis, I found growing very near to the old Bear Inn, close to the old postman's path, under shelter of a tall hedge, and nearly hidden with the long grass. I saw but one other orchis near the path, and that was a fine spike of *Orechis maculata*. At one particular part of the wayside, where a small rill of water was always running, there were large breadths of the lovely blue-flowered brook-lime, *Veronica beccabunga*. Some of the finest plants of burdock, *Arctium lappa*, that I remember to have seen. When this plant is found four or five feet in height, and furnished from the bottom upwards with branches, and covered with its beautiful mauve-coloured flowers, it is really a stately object. Very near the end of the old man's path, I found a large patch of hart's-tongue fern, *Scelopendrium officinarum*, growing on a hard clay-bank. In close proximity I found the male fern, *Lastrea Filix-mas*; the female fern, *Athyrium Filix-femina*; the prickly shield fern, *Polystichum aculeatum lobatum*; the crested fern, *Lastrea dilatata*; the prickly crested fern, *Lastrea spinulosa*; the royal fern, *Osmunda regalis*; the heath fern, *Lastrea Orocrotis*; the hard fern, *Lomaria spicant*; and the common polypody, *Polypodium vulgare*; last of all, but not the least beautiful, the common brake, *Pteris aquilina*, grew on the common sides through nearly the whole length of the road. Under the dense shade and shelter of a plantation of fir-trees at the top of the hill, some plants of the last-named species grew to the height of seven feet, with the fronds as gracefully and regularly arranged as an ostrich plume.

As the old man left the village of Oakshott, on the return journey, one of the most beautiful undulated landscapes anywhere to be seen presented itself, embracing Leatherhead Downs, Epsom Common, Kingston, almost round to Hampton Court, on the right; on the left, Box Hill and its environs, the view in this direction extending far into Hampshire. Seen from this point, the whole country is laid out in pasture and arable land, intermixed with large glades of common oak, elm, and rich masses of Scotch pines. On a fine summer evening, in the presence of such a view, one can hardly refrain from exclaiming with the bard of Inspiration, "The little hills rejoice on every side. The pastures are clothed with flocks; the valleys also are covered over with corn; they shout for joy, they also sing." It would occupy too much of the time of this meeting to enumerate all the plants which turned up as so many new creations in the postman's path; but there were many others of equal interest with those I have mentioned. There were several species of *Hypericum*, or St. John's Wort, with their bright yellow blossoms; several species of *Erysimum* and *Sinapis*; large breadths of the lovely germander, *Veronica chamaedrys*; wild thyme; several skull-caps, *Scutellaria*; the graceful base-rocket or English mignonette, *Reseda lutea*; several species of *Mentha*, or mint; a few rushes, many kinds of grass, and some interesting sedges, every individual of which, to the plant-loving passenger, would be an object of intense interest.

Extending our walk a little beyond the village, there are large patches of that most curious of British plants, the sundew, *Drosera rotundifolia*, covering large breadths in daup places. In association with this, the bog-asphodel, *Narthucium ossifragum*, renders itself conspicuous by its numerous umbels of rich orange-coloured flowers. That interesting parasite, the dodder, *Cuscuta epithymum*, is very abundant among the heath. This plant is supposed to arise from and derive its nourishment from the soil in the first instance, and as soon as it has made sufficient growth it attaches itself to a congenial plant, inserts its feeders into it, and thenceforth derives its nourishment from the plant to which it is fastened. Having established itself, it seems to detach itself entirely from the soil. I have examined several plants in various stages of growth, but have never been able to detect any connexion whatever with the soil. An interesting plant called *Hypericum erodes*, a water plant, and rare, I found in large quantity. I have never met with this plant in my peregrinations elsewhere. Not far from where I found this plant, I discovered large patches of the exquisite *Lycopodium inundatum*, or club-moss, covering wet places with its delicate transparent green, and as delicious to the touch and tread as the richest Turkey carpet. While speaking of the vegetable productions of this locality, I will only mention one more, and that is, I one day came across a patch of a most enchanting fungus of a rich vermilion colour. This was certainly one of the most strikingly beautiful things I ever recollect to have seen. They were growing on the margin of a pond, from a soil composed of the rotted leaves and twigs of fir-trees, under the shade of which they had acquired a large size, and the most exquisite colouring. Without particularizing, I will only add that this locality was rich in varieties of beautiful fungi. All the British heaths, with one exception, grew fine in this locality. About the middle of Oakshott Heath, I found a very fine patch of a white variety of *Erica cinerea*. The only iris indigenous to Britain, *Iris foetida*, I also found here, growing close to the footpath on the margin of a coppice.

I have been thus particular at the risk of tediousness, that any one visiting that locality may be able to recognize all the plants I have named in the positions indicated. These wayside plants have ever been to me sources of perennial interest. When I have been wandering through coppice paths, and by ditch-sides, and have been delighted with the manifold forms of beauty which have in succession presented themselves, I have frequently been reminded of the lament of the poet that

Full many a flower is born to blush unseen,
And waste its sweetness on the desert air.

But I am quite sure there is not a word of truth in it; wherever there is a plant growing or a flower blossoming, there is a present God, moulding into beauty and filling with fragrance these products of His special skill, and rejoicing in the work of His own hands. Does He not ask, "Who hath divided a watercourse for the overflowing of waters, or a way for the lightning of thunder; to cause it to rain on the earth, where no man is; on the wilderness wherein there is no man; to satisfy the desolate and waste ground; and to cause the bud of the tender herb to bring forth" (Job. xxxviii. 25-27). Do we not know that in places the eye of man has never seen, and upon which his foot has never trodden, numerous plants, animals, and insects of the most beautiful types abound, and there is no intelligent eye but His own to exult in the perfection of His various works? And that He does delight in His own work we learn from Genesis i.—that after evoking into being the various creatures of His skill and power, "God saw everything that He had made, and, behold, it was good." In passing

negligently by any of the works of His hands, though it be but a wayside plant we withhold from Him the tribute of admiration which is His right and reasonable due. It is a very significant fact that almost every highway is furnished with growths of green on either side. The beneficence of the Almighty Father is especially apparent in this arrangement. It seems to be an especial provision for the necessities of cattle, that they may have the opportunity of refreshing themselves as they pass from one place to another. All ruminating animals derive their chief support from the various grasses, and He who ordained that the mouth of the ox employed in treading out the corn should not be muzzled, has so contrived that the beasts of the field are enabled to crop the sweet, juicy, and nutritious herb from the margin of every pathway along which the demands of trade or the occasions of pleasure may require them to travel.

Pretty much the same description will apply to many of the pathways of our native land. In one locality one particular class of plants will prevail, and in another other classes will be more prominent. The configuration of the landscape will vary in every district, and in every part of the land, from whence a view of any extent can be obtained; the disposition of the hills, the general arrangement of the landscape in all its features, will suggest to the observer the consummate taste and unapproachable skill of the Great Architect.

One of the most exquisite of wayside delights is to be obtained from an observation of the innumerable trees growing in the gardens by the pathsides in the suburbs of towns, and in the parks and gardens of country places. The bursting of the buds in spring into masses of green of every shade; the development into blossom of the stately horse-chestnut, the elegant lathurnum, the delicious hawthorns of various colours, the fairy-like flowers of the common acacia, the noble panicles of the flowering ash, and the countless flowers of the Judas tree, covering every part of the stem, from the earth upwards to the tip of the remotest twig,—these delight the eye with their exquisite shapes and colours, and many of them convey very pleasurable sensations to the organs of smell. The beauty of these wayside trees is very much enhanced by the glowing tints of autumn. Nothing can surpass the glory and beauty of large masses of trees, when their leaves have assumed various tinges of yellow and gold, auburn and crimson, all blended so as to produce a most exciting and admirable picture; and though these appearances shadow forth decay and death, yet for the time they are among the most striking objects that can be looked upon.

The maple, the Liquidambar, the Virginian creeper, and some others of North American origin, have their leaves of a rich ruddy crimson before falling off.

Every wayfarer who has been overtaken by night has, whether he would or not, turned his eyes upward in admiration and wonder to the innumerable stars that twinkle above and around him, and many a time has been compelled to say with the astonished poet:—

Oh, what a confuence of ethereal fires
From urns unnumbered stream to a point,
And centre in my sight!

And the complete exactitude with which these bodies accomplish their revolutions cannot fail to impress one with the fact, that the Almighty Ruler stakes his veracity and faithfulness upon the unerring certainty of their motions: "Thus saith the Lord, If ye can break my covenant of the day, and my covenant of the night, and that there should not be day and night in their season; then may also my covenant be broken with David my servant, that he should not have a son to reign upon his throne" (Jer. xxxiii. 20, 21).

The wayfarer may have learned the great comparative magnitude of the heavenly bodies, may have learned something of their balancings, and of their necessary relations one to the other: he will be filled with wonder, astonishment, and reverence, and he will be compelled to acknowledge that such results can be the product of nothing short of infinite power, skill, and contrivance, and will probably express himself in some such words as these—

His arm Almighty put these wheeling globes
In motion, and wound up the vast machine.
He formed in His palm these mighty orbs,
And bow'd them flaming through the dark profound,
And set the bosom of old Night on fire.

The railway passenger who spins over a large breadth of country has abundant sources of delight in the rich corn-fields which in rapid succession present themselves to his view, and the pastures covered with flocks and herds. As he observes these, he perhaps wonders how it is that while sheep and oxen are feeding upon precisely the same herbage, it produces wool upon the back of one, and hair upon the back of another. Now the bold configuration of the ground, and the rich masses of the incumbent forest, astonish and delight him. Now he whirls through a cutting, and while he is knitting his brows and straining his sight to get a glimpse of the character of the strata through which he is passing, his mind recurs to that wonderful event when every portion of the earth's surface was whelmed beneath the mighty flood, and that particular portion of it through which he is now passing may have received its character from the settlements of the different materials which must then have been mixed up with the circumambient waters, according to their different degrees of gravity; and he admires the wisdom which has arranged these crude-looking substances—sand, stone, chalk, and a variety of other things—in such forms as that in a general way they turn out to be most useful to the inhabitants of those localities where they most abound. The railway traveller who passes frequently over the same ground may interest himself very much by watching the progress of vegetation on the banks—may, indeed, have special points of this sort, in which he may get to feel a growing interest. I could name several individual plants, and masses of plants, that I have watched with great interest for several years by the sides of a railway along which I have travelled nearly every week for some years past. I will only particularize one—that is, a very fine plant of *Lythrum salicaria*, or Willow-leaved Loosestrife, growing upon the right-hand bank from London, about half or three-quarters of a mile from the Sutton station, on the London Bridge and Epsom Railway. This plant always attains a large size, and every year has been crowned with large spikes of its rich rose-coloured flowers. Its integrity has been preserved every year by the men who mow down the herbage on the banks every season, until, in the course of the past summer, some barbarians ruthlessly cut it down.

Only one more; the railway traveller in a country like our own, which is for the most part under cultivation, has the largest opportunity of observing how beneficently and sufficiently all the wants of living things are provided for by the universal Father, and if he is at all disposed to recognize the hand of God in the plenty scattered along his path, he will detect himself involuntarily exclaiming with the shepherd-king, "The Lord is loving to every man, and His tender mercies are over all His works." Every wayside is strewn

with delights; every walk, every ride, at any time, in any place, abounds in objects of interest. From the lines I have read you will gather what are my own tastes, and to which part of the wayside I should turn in search of interest, if, indeed, interesting objects did not, as they mostly do, obtrude themselves upon my notice. I will finish this paper by saying, that my walk to this room to-night was fraught with interest. How so? did you admire the shops as you came along? No. Had you an agreeable companion to talk to? No. My thoughts were upon the pavement I walked upon. In admiration of the wisdom of God who had made such a material as Yorkshire paving, in such plenty as to enable us to pave our ways and thoroughfares with it, and who has given to men the wisdom and ability to extract it from its quarries, and shape it and make it contribute to our use and comfort as we journey along the ways of life: "All Thy works praise Thee, and Thy saints bless Thee" (Psalm cxlv. 10).

Calendar.

WORK FOR WEEK COMMENCING NOVEMBER 23.

Kitchen Garden and Frame Ground.

ARTICHOKES to be dressed for the winter by removing any late heads, the stalks of which can be inserted in a bed of earth under cover till wanted; next remove the large leaves, and mould up the plants without throwing any soil into the centre. As clippings of hedges and prunings of trees are generally burnt at this time of year, keep the ashes dry, and at the first opportunity after having earthed up the plants, spread the ashes two or three inches thick over the ground between them.

BEANS AND PEAS not yet sown for speculative crops may be got in now the weather is fine; the same sorts to be used as advised a few weeks back. Choose a dry sheltered position. If there is plenty of spare room in frames or pits, preparations may be made for early crops without incurring the risk of sowing out of doors. Fill a frame with turfs cut the usual width, and laid grass-side downwards. Sow the seeds pretty close together along the centre of each breadth of turf, and then sift over some fine soil just to cover them, and shut up. As soon as the seeds have started, give air cautiously, and keep them as hardy as possible. As they rise, occasionally add more soil, so as to keep earthing them up; this will make them more strong and stubby than by covering them their proper depth in the first instance. In February the turfs may be lifted out, and the plants divided without any injury to the roots, and so planted out in drills of well-prepared soil, and protected with long dry litter and reed wattles, until the weather allows of complete exposure.

BRUSHWOOD is of many kinds. Clippings of hedges and small prunings of bush fruits and trees are generally of no use for firewood, except in the furnace of a saddle or cannon boiler, for which in some gardens all such stuff may be used. But there ought to be no waste of anything that will burn, and at this time of year labour can generally be afforded to deal with these things in a way to economize every scrap. Lots of real good firewood may be looked out by first chopping and sawing up all loppings of fair size; at the same time large gnarled and twisted branches should be stored for rustic work. Many a gardener has to buy in spring stuff that he might have supplied himself with by a sorting of the timber obtained in cutting down old trees and in the clearance of old plantations. When the best of the stuff has been stored, char all that remains, and keep the ashes under cover for use. In charring, a flame should never be allowed; a smouldering fire reduces without waste; a flame wastes the best part of the material—that is, the charcoal. To prevent too rapid a consumption, keep the heap well covered with turf, clay, or other soil, so as to confine the heat and prevent too free an access of air.

GARNISHING AND FLAVOURING HERBS should be taken up and potted in case of severe weather. Parsley and mint are generally scarce in February, because there is no care taken in time to secure supplies. Large roots of parsley potted now will keep green and fresh till wanted. The roots of mint should be potted in leaf-mould, and the pots plunged in an asparagus bed, or placed on a flue to force it gently. Parsley may also be protected on the ground by means of hooped mats and litter.

Flower Garden.

ALPINES suffer more from wet than frost; choice kinds had best be potted and put in frames, as during January there is usually much havoc committed among alpins on rockeries. The only safe way to keep up a collection is to have duplicates of all the species in pots.

FLOWER BEDS not occupied should be deeply stirred and kept rough. The fear of an untidy appearance causes many a flower garden to get sour and full of vermin, whereas the soil should be as thoroughly broken and pulverized as that of the kitchen garden. The beds may be manured now where the positions are comparatively dry, but it will be as well to defer manuring till the spring. If supplies of turf are wanted for next year's potting, get the material in at once, and stack in long narrow ridges like dwarf walls.

GARDEN ROSES.—Useful varieties of roses which furnish an abundance of flowers, and contribute to the gaiety of the garden are always in request, and should have attention in these pages equally with varieties that are especially prized for exhibition purposes. Roses of this kind, however, are so valuable for the general purposes of amateurs, that it is doing good service from time to time to bring their claims and merits into light, though in so doing it may be necessary to go back to ancient lists. These free-flowering, pretty, and hardy kinds are capable of many interesting applications as objects of border decoration. Some form admirable bushes for the corners of intersecting walks, where they may be left to grow, sparsely pruned, in natural luxuriance; or they may be trained over rustic arches, improvised from spare branches of shrubs and trees, to form vistas from distant points of view. Others, again, are especially adapted to ramble over "banks and braes," among fantastic roots and stumps; or to form a canopy of blossoms for summer-houses and bowers. Others, again, will clamber skywards, flinging flowery festoons as they ascend; or serve to conceal rough fences, or unsightly boundaries, dotting that which would be offensive to the eye of taste with lovely and brilliant blossoms. One of the most interesting and beautiful methods of utilizing these roses is to bud the stronger-growing kinds with numerous other sorts of various colours. Another way in which these gems of the garden should be employed is pegged down in beds; white, yellow, rose, and scarlet charmingly intermingling, and if on their own roots, multiplying themselves year after year, till their owner could supply half a neighbourhood from their prolific suckers. Mere generalities, however, do not convey much practical instruction; let us, therefore, proceed to an examination of the kinds suitable for the purposes we have indicated. For instance,

let us take that old Bourbon *Armosa*, a kind hardly heard of nowadays. What a glorious thing for a bright ever-blooming bed! Rosy, double, and free to a degree, though small, and without much substance; like many others hereafter to be named, having no pretensions as a florist's flower, but invaluable for the bed or bouquet. Take others of the Bourbon class, which abounds in roses eminent for garden properties, such as *Acidalic*, *Bouquet de Flore*, *Comice de Seine et Marne*, *Emotion* (new), *Pierre de St. Cyr*, *Dupetit Thouars*, *Paul Joseph*, *Le Grenadier* (magnificent dark colours of various shades), *Paul et Virginie*, *Madame Desprez*, *Sir Joseph Paxton*, and *Bourbon Queen*, and we have a selection of hardy autumnal bloomers of different colours and habits, admirably calculated for numerous garden purposes, which will bestow upon us blooms when blooms are, alas, few and far between. Some of the true *NOISSETTES* are very rampant growers, and commendably persevering in habits of bloom. *Luxembourg* is an old variety of this kind, which will form a corner bush, and which, in three or four seasons' growth, will attain the size of a huge lilac-tree, large enough for a whole garden of other kinds to be budded upon it. Other desirable sorts among the Noisettes may be found in *Jaune Desprez* (unfortunately very tender), *Eclair de Jupiter*, *Vicomtesse d'Avesne* (I fancy this is a Noisette), *Ophirie*, a peculiar colour, *Triomphe de la Duchere*, *La Biche*, *Lamarque* (a show rose), superb on a warm wall; and their new congeners, *Louise Darzins* (which quite supersedes that old favourite, *Aimée Vibert*), *Madame Alfred de Rougemont*, *Lady Emily Peel*, and *Pavillon de Pregny*. These afford a completely different but not less useful class of border ornaments, for the choice of the cultivator of moderate desires, who has an eye for homely beauty, and is not craving after the empty honour of a prize-box at some second-rate show. Some of the older *HYBRID PERPETUALS* furnish us with fine specimens of the garden rose proper. What a chaste thing is *Noemi*! *Sydonie*, again, quite an enchantress, with globular blossoms of true pink, a rare colour in modern roses. In continuation of the older roses, we enumerate *Marquise Boella*, *Desgaches*, *Louis Bonaparte*, *Souvenir de Leveson Gover*, *Mrs. Elliot*, *Madame Laffay*, *Paeonia*, *Dr. Marx*, *Duchess of Sutherland*, *Baronne Prevost*, *Mère de St. Louis*, *Reine des Fleurs*, *Dr. Ruschpler*, *Pio Nono*, *Madame Phelip*, *Madame Place*, *Baronne Halletz*; and of modern, *Le Rhône*, *Jean Bart*, *Parmentier*, *Wm. Paul*, *Admiral Nelson*, *La Brillante*, *Thérèse Appert*, *Reine de la Cité*, *Triomphe des Beaux Arts*, *General Simpson*, *Ornement des Jardins*, near to scarlet, *Madame Bravy*, and *Lord Palmerston*, and we have a goodly array of pretty free-blooming varieties for almost any purpose our gardens require. To these may be added about a dozen of the finest roses we possess, so often enumerated it would be waste of space to repeat them here. We must yet take a passing look at the *CHINAS* that are specially useful. *Mrs. Bosanquet* is delicately beautiful, and decidedly still a first-class flower in the camellia-like style, which cannot be dispensed with for any purpose. The *Pink China* is also most useful, and there is a scarce variety called *Belle de Florence*, which we saw at Messrs. Lane's Nursery in the past summer, which makes a sumptuous bed of the most glowing pink colour. To these may be added *Louis Philippe*, *Archduke Charles*, the changeable rose, and *Cramoisie Supérieure* and *Fabvier* for bedding. But it is to the *TEAS* we must look if we desire true perpetuality, and it is to this class all the really continuous bloomers owe that valuable habit. The most hardy of this beautiful section may be adopted with safety in any warm and sheltered position not too far to the north, if a little temporary protection in the rough Hyperborean blasts. Unfortunately, these charming productions of nature are so delicate in constitution that they cannot bear even the smell of frost, so that if we wish to cultivate them under the open canopy of heaven they must, like our own beauties, have their winter furs and victorines, or something equivalent, unless under exceptional climes and conditions. Some, however, are more hardy than others, and such will be found among the following lists: *Buret*, *Bougère*, *Caroline*, *Devoniensis* (one of the earliest English-raised roses, and still unsurpassed), *Goubalt*, *Gloire de Dijon* (first-rate in every quality), *Madame de Vatry*, *Mareschal Bugeaud*, *Melanie Vilternoz* (a show rose), *Narcisse*, *Safrano*, *Madame Falcot*, *Sombrieul*; *Vicomtesse de Cazès* must be added, although so susceptible of the "winter's whip," on account of its continuous and prolific bloom. Thoroughly protect it, and although the upper shoots may be killed back, it will, phoenix-like, renew itself from the roots when touched by the revivifying beams of the summer sun. In connexion with the subject, the season of planting suggests a few directions for that operation. As soon as the ground is sufficiently dry to become friable, plant *at once*. The trees planted before Christmas gain half a season. Take care the briars and those on their own roots are not planted deeper than the collar; manettis can scarcely be too deep, but eradicate any too prominent eyes that can be detected. Let the soil be rich, the planting firm, the mulching thick, the watering in dry weather in the spring be copious, and with auspicious fortune there will be abundance of lovely blossoms to make the garden glow, to adorn the vases, and to decorate the button-hole.

Greenhouse and Conservatory.

ERICAS of the winter-blooming kinds are to be kept as well aired and as hardy as possible. When requiring water, give the roots a good soaking, choosing bright mild weather for it if possible, and repeat the watering the next day if any doubt whether the ball has been moistened through. After this, let them go nearly dry again, but never beyond a certain point of dryness, or the ball will get hard. The general stock of Cape heaths will bear a few degrees of frost without harm, if kept well aired at all favourable opportunities. What is most likely to injure them is a dry fire-heat, and a too dry state of the roots. But they will want very little water at this time of year, and should have no encouragement to grow.

CHRYSANTHEMUMS may be kept in trim to keep the houses gay for a long time yet, if a little care is bestowed on removing dead leaves and keeping the foliage healthy. Some of the later kinds will now be coming into bloom, and a little fire-heat will be good for them if the weather is severe. The whole stock should be looked over now to see that all the plants are tailed correctly, to prevent errors in propagating next spring. Put in cuttings at once of the varieties to be grown as specimens for next year. The mild heat of a bed of leaves will promote their rooting, and it is as well to give them a little help, as if they remain in the cutting pots a long time before they make roots, they get exhausted, and do not grow with a proper vigour. Remember that small cuttings make the best plants. We believe a good deal of the difference in specimens exhibited is owing to the mode in which the cuttings were struck. As size is of great importance in specimen plants, the sooner the cuttings are put in the better, that they may have a long season of growth.

HYACINTUS that have filled their pots with roots may now be pushed on by placing them over a moderate bottom heat. In the early vinery the dung-bed will answer admirably, as the vapour will give the foliage a rich green

healthy hue, and the flowers will come in fine spikes. But they must be prevented rooting down into the dung by being placed on flat tiles or slates.

THE AZALEA INDICA.—This noble plant is now in process of being forced, for the decoration of the conservatory, the first batch in good establishments usually coming to perfection in December, and being succeeded by others until May, when the pelargonium takes its place, as the most showy greenhouse plant. Though, in common with many other fine subjects, it is very easy to grow and flower the Azalea in perfection, it is nevertheless very easy also to make the plant a mockery of itself and its cultivator, or, I might say, its destroyer. I hope I shall not offend any of my readers by saying that amateurs rarely do this plant well, but professional gardeners are generally expert in handling it. However, should what I have said offend any one, I will endeavour to make amends by a short and useful essay on the subject. The plants are now at rest, or have lately been put into force. We will therefore consider their treatment as it commences from this season. The plants may be kept in a cool greenhouse, until the natural warmth of the advancing spring causes them to bloom naturally, or they may be made to bloom at any time during the winter by placing them in a genial temperature. If kept cool they require but little water during winter, but it is most important, winter and summer, never to allow azaleas to become dry at the root. If dried up for a week or two, as in some greenhouses they are, the flower-buds never open, except in the likeness of bits of chaff, which fall from a sort of leafy eye when the plant commences its spring growth. But if forced water must be supplied in exact proportion to the amount of heat, and the syringe must be used freely and frequently, not only to wet the leaves, but also the bark. A fierce or sudden heat is most injurious—more injurious, in fact, than a little frost to those treated on the cool system. Plants to be forced should be removed from the pit to the greenhouse, and, after a week or ten days, may go to the stove or forcing-pit. If the temperature can be regulated to a nicety, it ought to start from 50°, which will dispose them to move quietly, to 60°, which will cause a very promising swelling of the buds, and thence rise to 70°, which is the maximum heat for forcing this flower. A humid atmosphere is essential to success, and the plants should be as near the glass as possible, to enjoy all the light that they can have at this dark season. After the flowers fairly begin to open, cease using the syringe, but continue to give water in sufficiency at the roots; and once a week, from the first stage of forcing till the flowers are full out, give give them a dose of weak liquid manure made by steeping sheep or deer dung in a tub, and using the solution in a quite clear state. When fairly out, and indeed before they attain their fullest perfection, remove them to the conservatory, or wherever else they are to be exhibited, and maintain for them a heat as near to 60° as possible. When the flowering is over, the plants make their new growth for the season. Indeed, this often commences while the flowers are still at their best; and, in my opinion, the little tufts of emerald green leaves peeping out amongst the flowers intensifies the beauty of the plants; for what is colour, however rich, without a little green to give relief? But some cultivators nip out these shoots in order to preserve a dense and uniform mass of colour. Every one to his taste. All I need say on the subject is, that nipping out these shoots does the plants no harm, and so those who like to do it may. I am not in favour of turning out either camellias or azaleas during the summer. I know that in many gardens it must be done, because of the small extent of glass compared with the number of plants cultivated. Certainly the splendid camellias at Chandler's years ago, and in the present day at Messrs. A. Henderson's, Edgware Road, and at Messrs. Veitch's, Mr. Turner's, and in all the best managed private gardens, are always under glass. Travellers tell us that in their native climes these shrubs grow in damp shady woods where tall trees tower above them, and effectively screen them from the sun. Therefore, to be always under glass, and effectually shaded in the summer, is consistent with their natural habits. However, those who must put them out are advised never to do so till the end of May, then to choose for them a position equally sheltered from wind and sun. Azaleas forced early must of necessity make all their new growth in the house, and the best way to manage them is to carry them back after they have flowered to the pit, or house, in which they were forced, and there again let them have forcing treatment, say a temperature of 55° by night, rising to 65° or 70° by day, with frequent syringing and watering, to encourage a free growth. At the end of May, these may go out of doors with the rest, if "turning out" is the practice of the garden. The subject of repotting is one of great importance. Many of my best plants have been three years in their pots, but have been annually top-dressed with thoroughly-decayed cow-manure, assisted with liquid manure. As a rule, it is desirable to give them a small shift every year—that is to say, to shift them into the next size. Any larger shift is more harm than good. I prefer to shift them in autumn, after the growth of the season has become quite ripe, and I can feel the flower-buds in the points of the shoots. The operation is a very simple one. Turn out the plant, remove the crocks from the bottom of the hall; have the new pot ready to receive it, with crocks regularly arranged for drainage, and covered with a layer of tough fibry peat, or nodules of very fibrous loam. Lower the plant into its place without disturbing any of the roots, and fill in with a mixture of yellow loam, two parts; peat, one part; quite rotten dung, one part; and sharp sand, one part. Ram the stuff in firm all round, give one good watering, and set the plant aside till the time comes to force them. This process of shifting may be performed immediately after the flowering is over; but if shifted at that time, they should be placed on a bottom-heat of 65° to 70°, to promote the formation of the roots in the new soil. As for pruning, any moderate shortening-in may be done at any time, but the best time is immediately after flowering. We sometimes meet with old scrubby azaleas that have been much neglected. The best way to recover these is to keep them cool till March, and then cut them down to the shape and size required. Immediately after this operation, lay them on their sides on a moist propagating-bed, or on a very sweet dung-bed, giving no water at the root, but frequently plying the syringe with tepid water on the old wood. A heat of 70° is the utmost they should be subjected to, and indeed 60 degrees will suffice, if no more can be afforded. They will soon begin to bristle with little green shoots, and when these are half an inch or so long, knock the plants out of their pots, and pick the earth out from amongst the roots, and cut the roots back considerably, and finish by potting them in as small pots as they can be got into, to allow of an inch of fresh soil all round for the new roots to run into. They must be immediately stood on a tan-bed or on any surface heated to 70°, and there be kept in a sort of vapour bath, but have very little water at the roots until they are growing freely. Then gradually increase the supply of water to the root, and diminish the degree of humidity in the air, and you will in due time have a fine growth. This is a golden rule for grinding old people young in the queenom of Flora, and it applies particularly to hard-wooded plants that have become old and ugly, such as camellias, oranges, &c., &c.; but it does not apply to

heaths, for they will not stand the heat, and, indeed, the best way to treat old and ugly heaths is to throw them away. To propagate azaleas is a most easy matter, but success depends on taking the cuttings at the proper time. Take cuttings of the young shoots when they are about two inches long, when they are quite soft, but yet have made a good growth. The garden term for this condition is "half-ripe." If getting woody, they will not strike; if very sappy, they will quickly rot. Having made the cuttings, dibble them into silver-sand, sprinkle them slightly, cover with bell-glasses, and let them remain in a warm house for a week. Then place them on a bottom-heat of 60° to 70°, and keep them always moist, but never wet, until they begin to grow at the points, when the bell-glasses must be taken off. About a week after that, pot them separately in small pots filled with equal parts of peat and silver-sand, put them on a gentle heat, again use the syringe upon them regularly, and they will soon fill their pots with roots. You now have but to shift them on annually, and to pinch out the points of the young shoots to promote a bushy habit, and in due time they will repay you for your care. In selecting azaleas, a few of the most distinct and striking will serve the purposes of most cultivators. For those who love collecting there is abundant room for speculation and entertainment in this magnificent family, the varieties of which are very numerous. The following is a good selection of twelve old varieties:—Admiration, Criterion, Etoile de Gand, Extrani, Gem, Gledstanesi, Sir H. Havelock, Iveryana, Juliana, Perfection, Perryana, Variegata. Among varieties of more recent introduction, I would name as desirable, Oracle (F. and A. Smit), paper white; Reine des Pays-Bas, violet and crimson; Grande Duchesse de Bade, red and chocolate; Fascination (B. S. Williams), pink and carmine; Stella (Veitch), orange scarlet, the finest-formed azalea known; Vesuvius (Veitch), like Stella, and a very nice point to determine which is the best of the two; Splendidissima (B. S. Williams), red and white, striped like a carnation; Dieudonna Spae, salmon and white; Flag of Truth, semi-double white. I could name a hundred more without risking the introduction of a bad one, for they are all good. But I have named those that are most distinct in colour, most free to grow and bloom, and most perfect in the several properties required in these flowers. But I must not forget a few varieties that are worth adding to collections already formed. Most important, for the sake of its splendid golden flowers, is *Azalea sinensis*, a deciduous kind, which produces its flowers before the leaves. It is a grand conservatory plant, and nearly hardy, therefore do not force it in a strong heat. *Bouquet de Fleure* is a splendid hardy hybrid; the flowers are red, white, and yellow. *Petunia-flora* is a superb variety of the India race, which makes a fine contrast to whites and yellows in the conservatory, the colour being rosy purple. *Phœnix floribunda* is a good purple, not quite a show flower, but invaluable for decoration. Lastly, *Azalea obtusa* is a little rosy-flowered gem for the cool conservatory or greenhouse, and a good subject for forcing; and *A. amœna* is like it, but much hardier, and answers to perfection for the front of an American bed in sheltered places. Azaleas are subject to few diseases or insects when properly treated; but sometimes the best treatment will not prevent thrips. To deal with this pest, proceed as follows: Take five pounds of soft soap and dissolve it in ten gallons of rain-water; then add one gallon of strong tobacco water. Into this mixture dip the plants, and lay them on their sides, to prevent any of the mixture reaching the roots. In about half an hour (or less) after the dipping, wash them in a tub of soft water, and they will be as clean as if never a thrip had touched them. In the course of a fortnight repeat the process, which will kill any young that may have been hatched from eggs which the first dipping did not remove. The dipping does no harm to the plants provided it is not allowed to dry on them; hence it is I say wash them in half an hour or less. If too large to dip, wet them with the mixture by means of a syringe, taking care to lay them on their sides that the leaves may be wetted on both sides and the mixture prevented reaching the roots.

Stove and Orchid House.

ORCHID HOUSE to be kept at as low a temperature as is consistent with safety. The use of excessively high temperatures has been the cause of more mischief than all the rest of the mistakes in orchid culture. Keep the atmosphere of the house moderately dry, and as sweet as possible. One of the most important matters for the young beginner is to learn to decide when the pseudo-bulbs are ripe and ought to be at rest, and to proportion the period of rest to the habit of the species—matters which depend more on personal observation than on the precepts of books.

GESNERA ZEBRINA is one of the most useful of winter flowers, and should have every encouragement, for its exquisite leaves are almost as attractive as its scarlet and yellow flowers. They will require an average temperature of 65° to 70°, with plenty of water, and to be syringed occasionally while pushing for bloom; but this must be done with great caution. Any that are to be started now must be potted in a rather more peaty soil than for summer culture, and have very little water until in active growth.

EUPHORIA JACQUINIFLORA will soon be in fine condition, if carefully treated. Let it have good stove temperature and plenty of light, but be careful to give it very little water. It is often spoiled by amateurs, who think as the plant is in a flowering state it ought to have abundance of moisture, which is a mistake. If kept very wet at the roots, the leaves will fall off. At the same time it must not get dust-dry.

Forcing Pit.

PINES in fruit will need a moist air and a good bottom-heat. The general stock must have as low night temperatures as will be safe, say 55° for a minimum, and by day 70° to 75°, and not higher. Dung-heat is rather troublesome this time of year, and there must always be at hand materials for lining and covering up, in case of a sudden change to severe weather.

VINES in course of breaking may be assisted materially by making up in the house a large dung-bed. The dung should have been turned twice, then to be wheeled in, and made up solid as for a hotbed, but the surface not to be covered with soil. The ammoniacal vapour and the moisture together will give great vigour to the new growth, and if the roots are properly encouraged there will be a grand start made for an early crop. If this cannot be done, syringe frequently, and put troughs of water over the dunes or pipes. Vines now to be started should not have much heat, say 55° by day and 45° by night, to be increased gradually; in fact, any hurry in starting vines into growth has to be paid for afterwards in shanking, mildew, deformed bunches, or some other grievance.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a specimen copy free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

Correspondence.

A FOG IN THE FRUIT GARDEN.—I have been so bewildered by the several claims of rival systems of fruit culture, and the almost angry, but mostly cynical tone of the disputants, who have been airing their doctrines, and perhaps (who knows!) pushing their trade at the same time, by the aid of the great discussion, that I will not vouch for the truth of a single word I am now about to say, or for the soundness of any argument, or the reasonableness of any opinion. No man, so perplexed as I am, should feel confidence in himself; but, in spite of my confusion of mind, I have no confidence in any one else; so for the present I can see nothing but a fog in the fruit garden. That I have a fruit garden I am tolerably sure—would I were so sure of some other things I hope will prove true! yes, and I have some fruit too, the consequence, let me assure you, of doing the very opposite I was advised to do by the great adviser in whom once upon a time I put my trust. Let me unfold to you a page or two of my domestic history. I selected, I bought, I planted. I was under the spell of a book which taught me to prefer little trees to big ones, which taught me to chop off their roots and pinch back their heads, and generally speaking to starve, mutilate, and ultimately murder them; so that if the delusion lasted, I should soon want some more. Yes, I selected, I purchased, I planted. More than this, I actually believed that miniature trees would produce more fruit than mighty ones; that the more I cut away their roots and their branches, the more I pinched out the hearts of their summer growth, and laboured in various ways to debilitate them, the more fruit I should get. I even went so far as to believe that a paltry little apple-tree the size of a doll, a tree just big enough to adorn a window-sill, would produce fine apples. So I had a house built, and filled it with potted trees, and all went merry as a funeral bell; for many of my trees died, and the more I pinched, potted, and pruned, the more they refused the fruit I coveted. Yes, I was in for it heart and hand for orchard house and miniature fruit garden, and got a bushel or two of fruit of middling quality every year, in return for such an outlay in money and labour as ought to have secured me tons of fruit, and the most luscious ever ripened by the sun. In spite of the constant teachings of nature, I went on pinching, repressing, starving, deforming, and the more I laboured the less I got. I had followed my book, and spent my money, and seldom had an apple to eat. I began to think that the paradise stock must have borne the apple that Eve seized upon for the ruin of the world, and was therefore cursed beyond hope, and might have remained of that opinion had not my neglect of my orchard actually proved the means of its restoration. I left off pinching and pruning, and the trees grew with astonishing vigour, making stout strong shoots, such as they had never made before. I was astonished; the scene was changed, the very leaves appeared to know that the tormentor (that is me) had desisted, and were just twice as large, and ten times as numerous as heretofore. The first winter after this outbreak of new life in the trees, I had a careful pruning performed, sufficient only to shorten back the longest of the shoots, and cut clean away some that were shut out from light and air. There was less fruit than before in the summer that followed, but there was again a good growth, and the strong rods of the previous year were beginning to bristle with short stubby fruit-spurs. When winter came again, I was compelled to thin the plantation, owing to its crowded state, and I therefore transplanted about half the trees, leaving abundant space amongst them. The next summer there was an enormous crop. Since that happy epoch in my domestic history I have had abundance of fruit of all kinds, and I have learnt of a surety that a certain degree of vigour is essential to fruitfulness, and that before we trouble about any system of pruning, we must make sure first of healthy free-growing trees, and give them time to accomplish what is required of them. As for the orchard house, with its trees in pots, I give an opinion, founded on experience that I have paid for, that it is a more serious, because a more costly, delusion than the miniature fruit garden, with its starving stocks, punished roots, and pinched-in branches. Mine is now serving me well as a cool vinery, and the once potted trees are growing freely in the open quarters. When I want forced peaches, or early fruits of any kind, I will again have an orchard house, but never will I fid-fad with those little toys that, in return for labour that would suffice for half an acre of orchard, give you a couple of dozen or so of pears or plums, about which you are expected by advocates of the system to go into fearful ecstasies. Miniature trees and pinching and root pruning are all very well in their way, but let us not suppose, as some would have us do, that we must begin with trees so small we can scarcely see them, and then labour hard to destroy them in order to make them fruitful. You startled me the other day when you said on this subject, that inasmuch as there could be but so much fruit to so much fruit-bearing surface, stunted trees could be of little use for profit, for the simple reason of their smallness of bearing surface. Of course, you can't expect a billy-goat to drag a load that would be difficult for an elephant, and to trust for the filling of a fruit-store to a lot of paltry little bushes with constitutions undermined, and their remaining energies repressed by extravagant pinching, is simply absurd. I believe in pinching when performed with skill and with careful lifting to promote the formation of surface fibres, and moderate manuring to give the fruit some size and flavour, and, in short, with whatever assists nature, and with nothing that wars against her. As to the stocks that have been vaunted so of late, especially the quince for pears, I do not hesitate to say that, by skilful treatment, pear-trees grafted low may be brought into bearing very nearly as soon as the same kinds on the quince, and with the advantage of better trees at every stage of their growth. The paradise stock for apples is excellent if a moderate growth only is required, but let us have that moderate growth in its integrity; let us not starve, abuse, and mutilate the trees in the expectation that a destructive system of cultivation will render them fruitful. No, my doctrine is, train your trees to any form you please, practise pinching or long pruning at your discretion, but make all your plans subservient to the ruling principle, that a tree must be allowed to grow, and that with some degree of vigour, or it can never produce fruit. AN AMATEUR.

POYNTER'S EARLY PEA.—For justice sake, I have no doubt you will kindly grant me space in your paper to say that I fear you have been misled in your trial of peas, so far as my "stock" is concerned; it (my stock true) is not Early Frame, as I can prove by my customers, some of whom grow acres of both kinds side by side. Further, I have not Mr. W. Clark's name as a purchaser of my pea, the only London agents being Messrs. Veitch and Sons and Mr. B. S. Williams, and no peas sold as mine would be genuine without the label as enclosed. I have not "pushed" it as new at a big price, but as a stock second to none, a few pence over the price of the common stocks of early peas. I much regret that so useful a trial should be nullified by

any errors, as I believe it to be the duty of all seedsmen to fairly and honestly help all such, at whatever cost of character of their own "dear children." I may mention, in passing, that I believe my pea was fully, and I am sure fairly, tested with most of the early kinds extant, got from the growers direct by J. B. Saunders, Esq., The Laurels, Tamton; and should he see your paper, and would kindly give his experience on the matter, it shall settle it, so far as I am interested.

Tamton, Nov. 14, 1867.

ROBERT H. POYNTER.

Replies to Queries.

Subscriber.—1. Tarragon. 2. Chervil. 3. Burnet.

Books.—S. B.—A new work on variegated-leaved plants is announced for publication by Messrs. Bell and Daldy; it will be illustrated with coloured plates, and the descriptions will be contributed by Mr. Hibberd.—W.—You will find Mr. Grindon's "Manual of British and Foreign Plants," published by Pitman, Paternoster Row, invaluable. The price is about four or five shillings. It contains the names, natural orders, native countries, and uses of all the plants that are known to be in cultivation.—S. S.—The best book on British plants is that by Professor Syme, in course of publication by Mr. Hardwicke. A good cheap work is Deakin's "Florigraphia Britannica," published by Groombridge.

Ferns for a Balcony Case.—X. Y. Z.—We understand that your fern-case occupies the position of a window, partly projecting beyond the line of the house, and the whole being visible from the apartment, the aspect of the case being west, or nearly so. The ferns selected should be hardy, and it is desirable they should be of bold handsome form and evergreen. Plant them in a mixture of good turfy peat chopped up to the size of hazel-nuts, with one-fifth of silver-sand added. Before putting in the soil, lay down two or three inches of broken flower-pots and clean broken bricks, and over that an inch of charcoal; then add four to six inches depth of the mixed peat and sand. By proceeding in this way you will give the ferns a fair chance to live and thrive. Some of our friends think it sufficient to buy the ferns, and then plant them in such a way that they are sure not to live, or at best they live only, and do not thrive. The following, amongst hundreds that are suitable, are recommended for their fine appearance and hardy constitution: *Scolopendrium vulgare crispum*, *Scolopendrium vulgare lobatum*, *Polystichum lonchitis*, *Polystichum angulare imbricatum*, *Polystichum acrostichoides*, *Onoclea sensibilis* (deciduous, but fine), *Asplenium adiantum nigrum*, *Asplenium marinum*, *Asplenium angustifolium*, *Asplenium Michauxii* (last two deciduous), *Athyrium Filix-femina*, *Frizelia* (deciduous, very distinct), *Blechnum spicatum*, *Ceterach officinarum*, *Lastrea æmula*, *Polypodium vulgare Cambricum*, *Campotisorus rhizophyllum*, *Woodsia ohtusa*, *Cyrtomium falcatum*, *Woodwardia Japonica*, *Selaginella obtusa*. These twenty are easily obtainable at comparatively low prices; they are various in form and colour, and would make a fine group in a large balcony case.

Bulbs for plunging out.—S. B.—There is still good time to pot a lot of bulbs for plunging out in spring. We find that potting such things as hyacinths and tulips singly in 60-sized pots is better than grouping them in larger pots; we now deal with them in this way largely. If price is an object, obtain cheap mixtures of hyacinths; from these very good spikes may be obtained. A few of the most distinct tulips for colour will be the best or you; but you may have a few dozens each of all the cheaper sorts, taken at random from any catalogue without fear, for they are all good, and in a mixed border all will be useful. Procure the bulbs, pot them, and cover them with four inches of cocoa-nut fibre at once.

Zizania.—Mr. Hibberd has not published a work on ferns. You cannot do better for the British species than order Moore's "Manual of British Ferns," published by Groombridge and Sons; price 5s.

Flowering Shrubs.—J. Harris.—Plant in the front of your shrubbery plenty of *Weigelia rosea*, *Ribes sanguinea*, *Spiræa prunifolia flore-pleno*, double-flowering *Furze*, *Persian Lilac*, *Deutzia scabra*, *Forstytbia viridissima*, double-flowering *Peach* and *Plum*, grafted low down for bush-culture; *Berberis Darwinii*, *Berberis dulcis*, *Garrya elliptica*, *Ligustrum Japonicum*, and *Viburnum plicatum*, and you will have abundance of flowers, especially in spring. A few herbaceous plants, such as *Pæonies*, *Irises*, *Delphiniums*, *Aconitums*, *Lychnis*, *Lysimachia*, &c., are desirable elements in shrubbery borders, to render walks in summer and autumn agreeable.

Roses on Clay Soil.—G. B. B.—If you break up the soil well and manure liberally, all the roses in your list will thrive in your clay soil. Add to the list *Lord Nelson* and *Sir Joseph Paxton*, for the sake of their abundance of flowers. We should prefer for a windy place and a clay soil brier roses one to two feet high, but if they are well treated own-root roses, if vigorous varieties, will do nearly as well on clay as on loam. We recommend briars as likely to be best for you. The difference of price on which you remark is a matter on which we cannot offer advice. You will see beef, mutton, corn, &c., quoted from the market letters in the papers at different prices; at some nurseries they never part with a plant unless it has legs to stand upon and a head to prove its reality, at others the shadows of plants are thought good enough to sell. As a rule, the highest prices represent the best goods, whether plants or what else, though of course not necessarily so. Use your own judgment on that matter.

Paradise Stock.—Learner may find the paradise stock at almost every nursery in the country where fruit-trees are grafted. It is a variety of apple which produces an inferior fruit, but in constitution is peculiarly well adapted to furnish roots for the better varieties, and is as easily propagated from cuttings as currant-trees. There are two sorts of paradise—the English and the French; the first is the most hardy, but the second is preferable for warm climates. Both of them root freely near the surface, and being by no means luxuriant in growth, the trees grafted upon them do not attain to a great size; hence for dwarf bushes and low cordons the Paradise Stock is eminently useful.

F. B.—Roses should be manured annually. If the flue will not heat so small a house it is useless and absurd. Why, a little charcoal stove such as Joyce's would be better, because, though not a perfect mode of heating, it does produce heat and diffuse it kindly.

T. J.—The yellow sport from Autumn is a good pompon, and if not available for exhibition purposes, will at least be useful and valuable for the conservatory and for bedding. For the plunging system, it will no doubt be far preferable to *Berrol*, which for a long time past has been the best early yellow. You must obtain rooted cuttings from the shoots which bear the yellow flowers.

Salt for Asparagus.—Salt.—Asparagus beds may be dressed with salt at

any time without injury, but the most effectual and economical way of using it is to give a thin sprinkling once a month, from the end of March to the end of September, and to abstain from applying it during the remaining months of the year. There can be doubt at all that salt acts directly as nutriment to asparagus, and is especially useful in helping to maintain a moist condition of the soil during hot weather. This query has been replied to about a dozen times within the six years that you have been a subscriber; perhaps it would be well now to become a reader, if you should do us the great honour to subscribe any more. Should you write again in the same tone, your letter will be quietly committed to the flames.

Gleichenias.—Enquirer.—The splendid ferns of this family require careful management when young, and it is desirable always to give them as much warmth as they will bear without becoming rusty. The soil should be good turfy peat in a rather lumpy state, with quite a fourth part of silver sand and finely-broken charcoal added. The drainage of the pots should be perfect and the plants should always be grown in as small-sized pots as possible, over-potting being carefully avoided. Several of the new species thrive in the greenhouse if taken care of, but such as *G. dichotoma*, *G. furcata*, and *G. pubescens* require the stove. The one of which you send a pinna is *Microphylla*, which requires a warm greenhouse.

Cocoa-nut Fibre Refuse.—A Florist will find this material useful in propagating if mixed with an equal bulk of sharp sand. It matters not whether it is used in a brick pit, in boxes, seed-pans, or what else; if moderately moist, almost any sort of cutting will quickly root in it, provided of course that the temperature and humidity of the place where propagating is attempted are suitable. The refuse may be employed for the same purpose, without sand mixed with it, but the roots formed in that case are not such good roots as those produced when sand is added.

Colours of Flowers, &c.—Florist.—There is no published list of colours, or of terms employed in describing the colours of flowers. Nor is it desirable there should be; no, nor is it possible. Why, some people cannot see distinctions of colour that others see; and descriptions and definitions are of no use, if the sense needed for applying them is deficient. Pray understand that we are not hinting that you cannot detect any and every shade of colour; of your ability in that way we know nothing; but, to speak of this matter to any useful purpose, we feel that the matter of chief importance is that individuals differ in their relative powers of distinguishing shades of colour, and the best possible rules, therefore, would be variously interpreted. A few years' practice in judging at exhibitions, and describing plants and flowers, would convince any one of the utter impossibility of reducing chromatic nomenclature to anything like system.

IS LICHEN-GROWTH DETRIMENTAL TO FOREST AND FRUIT TREES?

The following is the substance of a paper "On the Relations of Lichen-growth to the Health and Value of Trees and their Products," recently read before the British Association, at Dundee, by Dr. Lauder Lindsay, of Perth:—

There is, it would appear, a radical difference of opinion between lichenologists on the one hand and arboriculturists on the other, as to the effect, on the value of the timber and bark of the trees on which it occurs, of Lichen-growth. Lichenologists have been in the habit of describing lichens as deriving their nourishment *wholly from the air*, as non-parasitic, and as making use of trees simply as *bases of support*. Some, especially of the earlier, writers not only deny any possible harm, but demonstrate a considerable amount of actual good, in so far as lichens attract moisture to the trees on which they occur, and thus assist in their nourishment and growth. All "practical men," on the other hand—all those who are concerned with the cultivation of timber, bark, or fruit trees—without theorizing on the subject, are unanimous in describing lichens as detrimental to growth, and as depreciative of value. My friend Mr. Anderson, of the Kinnoul Nurseries, Perth, tells me that trees or shrubs coated with lichens are "immediately discarded as unsaleable," while Mr. Bell, factor on the Kinfauns estates, gives me a similar assurance as to the diminished value of oak-bark when infested by lichens. Mr. Gorrie, horticultural editor of *The Farmer*, and one of the most experienced and discriminating arboriculturists in Scotland, Mr. Moore, of the Sydney Botanic Gardens, New South Wales, and other practical authorities, whose opinions carry great weight on such a question, have borne similar testimony. My inference from this testimony is that they regard lichens as *true parasites*, living, in great measure at least, at the expense of the bark on which they occur—interfering with its healthy action and growth. While regarding lichen-growth, however, as, in a certain sense, or in some measure, a *cause of unhealthiness or disease* in the trees which it affects, they also admit that, in a certain other sense, it is a *result of unhealthiness or disease*. The evidence appears uniform that lichen-growth should never occur in forests or nurseries which are the subject of proper care, where the trees or shrubs are properly thinned, where the conditions of healthy growth are sedulously provided. Not only so, but I am assured that the disease of lichen-growth, when it occurs, can be removed or dissipated by removal of the tree which it affects to more favourable conditions of development. Mr. Moore, of Sydney, tells me he has seen lichen-growth disappear from a tree simply by transferring the latter to a richer soil or more favourable locality, or by supplying it with proper manure.

It is inconceivable that there should be such unanimity of opinion among arboriculturists, totally devoid of bias or theory, and expressing only the results of repeated observation in very different quarters of the world, without the existence of some good ground for their assertions. My impression is that arboriculturists are right to a greater extent than are the lichenologists, and that lichens must be regarded as, in some measure at least, *parasitic*, drawing the constituents of their *thallus* from the objects on which they grow. I pointed out in 1856, in my preliminary work on "British Lichens" (p. 50), that the filamentous lichens belonging to such genera as *Usnea*, *Ramalina*, *Evernia*, and *Parmelia*, which coat with shaggy flowing masses oak, fir, and other trees, and whose growth is the main subject of dispute between lichenologists and arboriculturists, contain such bases as silica and alumina, lime, potash, and soda, magnesia, manganese, and iron, in combination or not with carbonic, sulphuric, hydrochloric, phosphoric, or other acids. The most of these inorganic constituents could not have been derived from the atmosphere, and, indeed, we are shut up to the conclusion that, as in the case of higher plants, they are derived from the surfaces or substances on which the lichens containing them grow. This conclusion is further supported by the recorded facts that chemists have detected iron in greatest amount in species affecting ferruginous soils, and silica in those growing on quartzose or rocks or their debris.

I am not, however, prepared to contribute any new facts towards the

settlement of the interesting question which forms the heading or title of this communication, or of the other equally interesting, but less practical and economically important, questions which naturally suggest themselves for consideration in connexion therewith. My purpose is rather to call attention to the paucity and unsatisfactory character of the facts or opinions that have hitherto been recorded, and to invite the record of *facts*, as contradistinguished from mere *opinions*, bearing upon the following points more especially:—1. What are the precise grounds on which the assertion is founded that lichen-growth is detrimental to timber and other trees? 2. In what way does such growth injuriously affect the timber, bark, fruit, or foliage of such trees? 3. How far is lichen-growth a *cause of unhealthy or diseased development* in the trees on which it occurs? 4. How far is it a *result of such development*? 5. To what extent do lichens draw their constituents, *A. organic* and *B. inorganic*, from the *atmosphere*? 6. To what extent from their *bases of support*—the bodies on which they grow?

ON THE NOMENCLATURE OF PLANTS AND FLOWERS.

Among the difficulties connected with horticultural pursuits, that of the nomenclature of plants and flowers, derived from the classical languages, is often a drawback and discouragement, especially to the unlearned. This difficulty, however, is more apparent than real; for the recollection of a few simple principles, which most of us have had enforced at our fingers' ends in the days of boyhood, a limited number of descriptive words, and a Latin dictionary, will suffice to elucidate even the most recondite terms to be found in the catalogues, beyond which, in the present paper, it is not proposed to treat.

In the first place, the adjective must agree in gender and number with the noun, or word to which it is added to describe some circumstance respecting it. We have only, therefore, to consider or ascertain the gender and number of the noun to know what the termination (where there is more than one) of the descriptive word should be. Thus in "*Acacia armata*," the noun *Acacia* being feminine, we must say "*armata*," and not "*armatus*" or "*armatum*." "*Abutilon*" (bearing in mind that Greek nouns in *on* are equivalent to Latin in *um*) must have "*insigne*," and not "*insignis*."

The second case is where the descriptive word is intended to denote the discoverer of any specific production, or the person after whom it is named. Here we have the rule, "that the word or words specifying, 'belonging to,' or 'the possessor,' must be put in the genitive case." Drummond's Phlox will therefore be written *Phlox Drummondii*; Atkins's Cyclamen, *Cyclamen Atkinsii*, and so on.

Thirdly follow certain terminations, such as "*ensis*," denoting the habitat, or place where the plant is naturally found—for example, *Plumbago Capensis*, or *Cape Plumbago*; *Hydrangea hortensis*, or *garden hydrangea*. Analogous to this are the suffixes "*oides*" or "*ana*," signifying "likeness to"—as "*jasminoides*," "*Atlecana*," "*ceus*," consisting of; "*osus*," full of or abounding in, as "*globosus*," very globular; "*bundus*," abounding in, as "*floribundus*," "*ssimus*," the superlative of a quality; "*lus*" or "*ulus*," diminutive; "*formis*," relating to shape, &c.

The principal parts of plants or flowers, the peculiarities respecting which originate distinctive names to the variety, are commonly the roots, the inflorescence, the foliage, the calyx or flower-cup, the pericarp or seed-vessels, the corolla or blossom, the pistil, the seed, and the nectarium or honey-cup.

Some of the most common adjectives used in floral nomenclature follow below:—

		COLOUR.		
Striat-us,	-a, -um,	-a, -um,	striped.	
Nitid-us,	-a, -um,	-a, -um,	shining.	
Rose-us,	-a, -um,	-a, -um,	rosy.	
Violace-us,	-a, -um,	-a, -um,	violet.	
Alb-us,	-a, -um,	-a, -um,	white.	
Ni-ger,	-gra, -grum,	-a, -um,	black.	
A-ter,	-tra, -trum,	-a, -um,	purple.	
Purple-us,	-a, -um,	-a, -um,	scarlet.	
Coccine-us,	-a, -um,	-a, -um,	painted.	
Pict-us,	-a, -um,	-a, -um,	two-coloured.	Tricol-or—oris, three-coloured; &c.
Bicol-or—oris,	two-coloured.	-a, -um,	yellow.	
Lute-us,	-a, -um,	-a, -um,	spotted, or stained, or blotched.	
Punctat-us,	-a, -um,	-a, -um,	variegated.	
Yittat-us,	-a, -um,	-a, -um,	green.	
Maculat-us,	-a, -um,	-a, -um,	blue.	
Variegat-us,	-a, -um,	-a, -um,	crimson.	
Virid-is,	-e, -um,	-a, -um,	pearl-like.	
Cœrule-us,	-a, -um,	-a, -um,	saffron-yellow.	
Kermesin-us,	-a, -um,	-a, -um,	red.	
Margaritace-us,	-a, -um,	-bra, -brum,		
Croc-at-us,	-a, -um,			
Ru-ber,	-bra, -brum,			
FOLIAGE.				
Umbellat-us,	-a, -um,	-a, -um,	shadowy, or umbrella-like.	
Cremulat-us,	-a, -um,	-a, -um,	crimped.	
Racemos-us,	-a, -um,	-a, -um,	very branching.	
Frondos-us,	-a, -um,	-a, -um,	very frond-like.	
Fimbriat-us,	-a, -um,	-a, -um,	fimbriated, or fringed.	
Hirsut-us,	-a, -um,	-a, -um,	hairy.	
Acuminat-us,	-a, -um,	-a, -um,	pointed.	
Dentat-us,	-a, -um,	-a, -um,	toothed.	

And many others. "*Phyll-us*," -a, -um, and *folium*," leaved; "*macro*," large; "*micro*," little or small; "*microphyllum*," small-leaved; "*buxifolium*," box-leaved; "*bilobatus*," two-lobed, &c., will serve to illustrate these.

SIZE, HABIT, AND APPEARANCE.

Major, greater; minor, less; *nanus*, a, um, dwarf; *giganteus*, gigantic; *magnificens*, magnificent; *splendens*, splendid; *reticulatus*, netted; *arundus*, spined; *regalis*, royal; *virgatus*, twiggy; *gracilis*, slender; *floro-plenus*, full-flowering; *erectus*, erect; *glandulosus*, glandular; *plumosus*, plume-like; *affinis*, connected with; *lanceolatus*, lance-like; *ensiferus*, sword-like; *corymbosus*, in corymbs; *venustus*, comely; and many other terms, readily to be found by reference to any ordinary Latin dictionary.

The subject is of too extensive dimensions to be treated exhaustively in a single paper. Sufficient, however, has been indicated to popularize the subject, and to enable any ordinary reader, with a little patience, to obtain an insight into the meaning of most of the names of plants and flowers, and with some botanical terms commonly to be met with.

The Gardener's Magazine.

SATURDAY, NOVEMBER 30, 1867.

THE TEMPERATURE OF PLANTS DURING THE NIGHT is always lower than during the day where nature is undisturbed, but in plant-houses of all kinds it is occasionally otherwise, especially at this time of year. It is quite certain that an excess of heat during the hours of darkness is directly injurious to plants, and the cause of many of those morbid affections about the symptoms of which we hear much, and the causes of which we hear little. The forcing of seakale is a good illustration of the evils of undue night temperatures. In this instance we want an unhealthy or unnatural production, and we obtain it easily by means of *heat combined with darkness*. But there is no substance, little nourishment, and no constitutional vigour in the blanched shoots of seakale. If those same shoots had to make plants, they would be the most miserable plants ever seen, that is to say, if they ever became plants at all, and it is a question if that would be possible. Now it is a strange thing that thousands of cultivators who are well advertised by the artificial character of seakale, nevertheless, load on the fuel towards nightfall, and compel their plants to make long, weak, half-blanched shoots, when, as they know, a short growth, or no growth at all, would be preferable.

It is a fact of the utmost importance that plants of *all kinds* will bear with impunity a lower night temperature than is customarily recognised in the management of plant-houses. In the most torrid regions of the globe, the temperature at night is frequently very low. Readers of the Rev. J. D. Hooker's Himalayan Journal will remember the records of orchids and hoar-frosts; and readers of Livingstone will call to mind his accounts of chilly nights on the Zambesi. Everybody, that is to say everybody who reads, is familiar with the fact that in the hottest parts of Hindostan, and in the hottest seasons, the temperature of the air at night is commonly twenty, thirty, and even forty degrees below the temperature at midday, and that ice is manufactured by simply pouring water at nightfall into the saucer-shaped hollows scooped in the earth, the rapid evaporation from which, combined with active radiation, produces so low a temperature that ice is quickly formed, and is gathered up for the next day's comfort of the "sahib." If we were to be taught by some gardeners who take a pride in calling themselves "practical men," we should believe that Sir Cresswell Cresswell had been called upon to pronounce a divorce between Heat and Light, and had obsequiously complied; yet we may be pretty well sure he never did anything of the kind, for he was one of those good men who believed that in the realm of nature truth was to be found. High night temperatures are most injurious to plants, no matter from what part of the globe they come. A general rule can be given in respect of the temperature to be kept at night, and it is simply this, that it should be *always lower than during the day*. In many gardens the fires are lighted about 4 p.m.; by 6 p.m. there is a kindly heat diffused, or it may even happen at 4.25, for some of the tubular boilers demand only fifteen to twenty minutes to send thermal telegrams all over the place (at a great price in coke!), and forthwith the temperature of every house so fed rises, and the *heat increases as the darkness increases*, and that is PLANT MURDER. Do not suppose, good reader, that it is only in remote and very darkened districts this takes place. Nothing of the sort. The mischievous system is in action in the garden whence this is written; the fires are lighted late in the afternoon, and the houses are comfortably warm after dark, and the plants are already becoming long-jointed, pale, and attenuated; the Dæmon of *fire-heat without light* has got possession, and will for a time have his way. But that need not prevent us raising the warning voice. Gardeners, nurserymen, whatever ye are, keep down the night temperature, and if you want growth let the glass rise by daylight, and whatever growth is then made will be green and worth having.

No. 135, NEW SERIES.—VOL. X.

PRESENTATION TO MR. MITCHELL.—A very handsome tea and coffee service and timepiece in marble were presented to Mr. Mitchell (now of the firm of Lamont & Mitchell, Edinburgh), on the occasion of his retiring from the charge of the Palace Gardens, Hamilton, to engage in the nursery and seed trade. It was presented last Friday (15th inst.), at a dinner in the Douglas and Clydesdale Hotel, Hamilton, presided over by J. C. Forest, Esq., banker, Bailie Thorburn being croupier. Upwards of forty gentlemen were present.

AUCUBAS IN FRUIT have ceased to be rarities, but hitherto very few have been seen in the open air. In the garden of Thomas Bewley, Esq., Rockville, Dublin, there are some fair-sized garden bushes quite loaded with berries. Their colour is at present yellowish green, but as the season advances they will ripen to a lustrous red. Hitherto it has been considered essential to apply the pollen by hand for the fertilization of the plant, but in this case there was no manipulation performed; one small plant was placed in the vicinity of the trees, and the present crop of berries is the result. An oft-repeated query is thus answered. Cultivators have asked if there is any chance of the female aucubas becoming fruitful without the aid of skill, and it is evident there is a very fair chance indeed; we may even venture to say that, wherever a few males are planted near or amongst females, the berries will be produced in abundance.

THE BIRMINGHAM EXHIBITIONS of cattle, poultry, implements, &c., in the Bingley and Curzon Halls, will commence on Monday, Dec. 2, and close on Thursday, Dec. 5.

THE SMITHFIELD CLUB CATTLE, ROOT, AND IMPLEMENT SHOW, in the Agricultural Hall, Islington, will commence on Monday, Dec. 9, and close on Friday, the 13th.

Exhibitions of Chrysanthemums.

SOUTH ESSEX.

This society's exhibition, in the Artillery Hall, Stratford, was undoubtedly the best of the season in the neighbourhood of the metropolis. The hall is of ample dimensions, clean, cheerful, well lighted. Unfortunately for a chrysanthemum show the walls are wainscotted with varnished oak or an imitation thereof, and the bright brown colour of this is decidedly prejudicial to the colours of the flowers. A clear neutral gray, or a decided dove-colour, would no doubt be the best background for relief to the numerous half and quarter tints that prevail amongst chrysanthemums; at all events, the brown of new varnished oak, or oak-stain, is not desirable, and in the present case the exhibition was in some degree marred by it. The committee had foreseen this, and had to some extent neutralized it by freely hanging the walls with wreaths and chaplets of evergreens. This part of their work was admirably done, and this beautiful apartment was rendered additionally elegant by the bold lines and circles of deep green that were carried round the walls. The judicious staging and grouping of the plants and flowers resulted in the production of a grand effect, and we must not forget that several of the plants were of such dimensions and perfection as to enhance the dignity and richness of the groups in which they occurred, while attracting attention and admiration for their individual merits. There were three immense groups, placed on three several sides of the hall, forming three splendid and harmonious pictures. In the classes there was abundant competition, and in general quality throughout plants and flowers were in several cases superior, and in all cases equal to, the best at other exhibitions of the season.

PLANTS.—There was a special competition for a plated tea-service, value £5, the group to comprise not less than 20 plants. The schedule said, "It is expected by the contributors to this prize that the collections competing will be of a superior character (quality and general effect will be the leading features in this class). The judges are therefore empowered to withhold the same from any group," &c., &c. The three groups put up were all characterized by their superior character, and the first prize was most properly awarded to Mr. Simmons, gardener to Mr. Alderman Finnis, Wanstead, for a group which was perfect as to the style, size, and colours of the plants, and as to their grouping. The colours were balanced perfectly, and the arrangement of the plants was such as to carry the eye up successively from plant to plant till the crown of the group was reached, and that consisted of a gigantic plant, superbly rounded and finished, and covered with rosy flowers. The second place was given to Mr. Whitbread, gardener to — Sewell, Esq. There were some grand plants in this lot, but there were also a few rather past their heyday, and a couple of dark pompon standards, balanced with a yellow standard for a centre to them, detracted much from the effect. These dark pompoms (they were plants of Bob, no doubt) were inconspicuous, and hence the places where they stood appeared more like black holes in the group. A pair with rosy or purple flowers would probably have shown more freshly and effectively. Mr. Donald, gardener to J. G. Barclay, Esq., had the third place. Now Mr. Donald had some finer plants than Mr. Whitbread—some, indeed, of the finest plants ever seen—but there was a want of uniformity, some specimens having just turned the corner of absolute perfection. Nevertheless, taking them plant for plant throughout, there can be no doubt that Mr. Donald's lot was the best of the two left after the first prize was disposed of. And here arose the nice point for the judges, who must have passed a few anxious moments in deciding the matter. Well, the judges did right, no doubt, in putting this lot third; for it was most unskillfully grouped, and in several parts of it the combinations of colour were in the worst possible taste. Mr. Donald is one of the best specimen growers, no matter what subject he takes in hand, amongst a thousand who call themselves such. If he will give his mind to the study of colour as he has to cultivating, he may splendidly efface the recollection of being third in this grand competition by taking first against all comers. Another special prize was

offered by Mrs. Hilleary for the best collection of twenty plants, consisting of poupons, ferns, and fine-foliaged plants. The first place was taken by Mr. Low, gardener to Lieutenant-Colonel Capper, M.P., Upton, with a pretty and very bright group, in which bush poupons predominated. 6 *pyramid pompons*: first, Mr. Low, with fine specimens of Cedo, Golden Cedo, Mr. Astie, St. Thais, Calliope, and another; second, Mr. Whitbread, with General Canrobert, white and golden Cedo, Calliope, Hélène, Salomon. Mr. Lucas and Mr. Donald also contributed. 4 *dwarf pompons*: first, Mr. Low, with Lilac Cedo, Hélène, Madame Eugène Domage, and Antonius. 3 *standard pompons*: first, Mr. Low, with neat fresh table plants of Madame Eugène Domage, Salomon, and Cedo Nulli; second, Mr. Lucas, gardener to Miss Drake, Leytonstone, with Antonius, Bob, and Fanny; third, Mr. Whitbread, with Golden Cedo, Madame Rousselon, and another; fourth, Mr. Simmons. The third and fourth lots were larger than the first and second, but they wanted finish and were too coarse for any but the roughest conservatory purposes. 6 *large*: second, Mr. Donald, with good plants of Antonelli, White Christine, and Bixio. 3 *large* (amateurs' class): first, Mr. Parker, with Lady Harding, fine; Annie Salter, and Golden Christine. *Single specimen in any sized pot*: first, Mr. Simmons, with a finely-grown White Christine in a 20-inch pot; the plant measured over head from edge to edge 8 feet, and through from edge to edge at the base 5 feet 6 inches.

CUT FLOWERS, 24 incurved: First, Mr. Hilleary, of Ilford Road, with superb examples of Queen of England, Golden Beverley, Dr. Brock, Eve, Duchess of Wellington, Prince of Wales, Cherub, Mrs. Cunningham, Little Harry, Fingal, Mrs. Brunlees, Venus, Jardin des Plantes, Mrs. Haliburton, White Globe, very fine; General Bainbrigg, Selina, Lady Harding, Lady St. Clair, Golden Dr. Brock, Prince Alfred, Lady Slade, Mrs. Heale. Second, Mr. Donald, with White Globe, Venus, Mr. Jay, Prince Alfred, Lady Slade, Rev. J. Dix, Duchess of Wellington, Yellow Perfection, and others. Third, Mr. Whitbread, with Princess of Wales, St. Patrick, Dr. Brock, Lady Slade, Prince Alfred, Jardin des Plantes, and others. Fourth, Mr. South, gardener to — White, Esq.—in this lot a fine Empress of India. 12 *incurved*: First, Mr. Beadle, gardener to — Cottan, Esq., Wanstead, with Empress of India, Prince Alfred, General Bainbrigg, Themis, General Slade, Bella Donna, Goliath, Venus, Dupont de l'Eure, Jardin des Plantes, Novelty, Princess of Wales. Second, Mr. Brown, gardener, to — Ellis, Esq., Abbey Wood, Kent, with White Globe, Goliath, John Salter, Prince of Wales, Golden Beverley, and others; fine. Third, Mr. South. Extra prizes to Mr. Whitbread and Mr. Hodson, gardener to G. Harcastle, Esq. 12 *incurved (for amateurs only)*: First, R. G. A. Hilleary, Esq., with Jardin des Plantes, Prince Alfred, Golden Beverley, Lady Slade, Duchess of Wellington, White Globe, Golden Dr. Brock, and others. Second, Mr. Greenfield, with Beverley, Prince of Wales, Prince Alfred, and others. Third, Mr. Shipman, with a fine Beverley, and others. 6 *incurved*: First, Mr. Browne, with Prince Alfred, White Globe, Prince of Wales, Goliath, Bella Donna, Golden Beverley. Second, Mr. Beadle; third, Mr. Lucas; fourth, Mr. Simmons; extra, Mr. Hodson. 6 *incurved (for amateurs only)*: First, Mr. Greenfield, with Rev. J. Dix, Prince of Wales, Prince Alfred, Beverley, Dr. Brock, White Globe. Second, Mr. Shipman; third, Mr. Shippett. 12 *reflexed*: First, Mr. Donald, with beautiful examples of Prince Albert, Ariadne, Sabrina, Alma, Lord Clyde. Second, R. G. A. Hilleary, Esq., with a fine Progne, Attraction, Madame Leo, and others. Third, Mr. Whitbread. 6 *large Anemone-flowers*: First, Mr. Brown, with Lady Margaret, Madame Goderau, Mrs. Peters, Louis Bonamy, Prince of Anemones, Gluck. Second, Mr. Hilleary; third Mr. Whitbread. 12 *Anemone-pompons, in bunches of three each*: First, R. G. A. Hilleary, Esq.; second, Mr. Donald; third, Mr. Brown; extra Mr. Parker.

There were three beautiful collections of fruit, the best being that sent by Mr. Donald, comprising fine Black Hamburg and Chasselas Musqué grapes, apples, pears, &c. 2nd, Mr. Groves, of South Grove, Mile End. 3rd, Mr. Deacon. Mr. Burton contributed the best design for garden; 2nd, Mr. Beadle. Several handsome ferns were shown, and the miscellaneous subjects added very much to the interest and beauty of the exhibition.

EAST LONDON.

The exhibition by this society in the Vestry Hall, Bow, was one of the best the society has held, and proved attractive to a large concourse of visitors. One of the special attractions was a group of fine-foliaged plants, supplied by Mr. Prestoe, of Victoria Park, many of which were remarkable for their beauty and rarity. Mr. Wilkinson, of Mile End Nursery, sent a group of ornamental plants, and Mr. A. Forsyth, of Brunswick Nursery, Stoke Newington, contributed a great collection of specimen chrysanthemums, both large-flowering and pompon varieties, and several stands of cut flowers. Mr. Allen, of Norfolk Nursery, Shacklewell, embellished the table on which the cut flowers were staged with the silver épergne, with which he was lately presented by this society, with flowers; and there were many miscellaneous contributions, of scarcely less importance, to vary and enrich the exhibition.

PLANTS.—Mr. Ford presented the best collection, the plants being fresh and in fine condition as to flowers. 2nd, Mr. W. Greve, with a beautiful lot. 3 *specimen pompons*: 1st, Mr. Lowe, with neatly-trained and richly-flowered plants of Madame Eugène Domage, Hélène, and Lilac Cedo Nulli. 4 *specimen pompons*: 1st, Mr. Lowe, with Calliope, Cedo Nulli, Golden Cedo Nulli, and St. Thais. 2nd, Mr. Whitbread, with good examples of General Canrobert, Bob, and another. 3 *specimen chrysanthemums, large flowers*: 1st, Mr. Parker, with well-trained plants of Lady Harding, Annie Salter, and Golden Christine. In an extra class for 3 *specimens, large flowers*, 1st, Mr. Whitbread, with Christine, Jardin des Plantes, and White Christine; fine. 2nd, Mr. Drain, of Southgate Nursery, Kingsland, with Christine, White Christine, Golden Christine. 3 *plants without stick or tie*: 1st, Mr. W. Grovo. A good class, because the generally ragged and disorderly appearance of the plants furnishes a powerful argument for careful training and tying, without which no specimen can be fit for presentation.

CUT FLOWERS.—24 *large incurved*: 1st, Mr. Waites, with Prince Alfred, Lady Slade, Mrs. Heale, Lady Harding, Lady St. Clair, Golden Dr. Brock, White Globe, General Bainbrigg, Selina, Jardin des Plantes, Beverley, Mrs. Haliburton, Fingal, Mr. Brunlees, Venus, Cherub, Mrs. Cunningham, Little Harry, Prince of Wales, Duchess of Wellington, Eve, Queen of England, Golden Beverley, Nonpareil. 2nd, Mr. Whitbread, with a fine lot, comprising Prince Alfred, Lady Slade, Dr. Brock, Princess of Wales, Golden Eagle, &c. In two other classes for 24 *incurved*: 1st, Mr. Hawkes, with a beautiful lot of flowers, Beverley and Yellow Perfection being extra fine. Mr. Ford second in each case. 1st 12, Mr. Schrier; 2nd, Mr. Joffery. 1st 6, Mr. Hawkes; 2nd, Mr. Ford. 36 *large anemone-flowers, with foliage*: 1st,

Mr. C. Parker, with Antonius, Roso Margaret, Astrea, Perle, &c. An extra prize for 6 *large anemone-flowers* to Mr. Grace, who showed fine samples of George Sand, Prince of Anemones, Fleur de Marie, and others. Mr. Sinclair presented a beautiful group in this class.

The best collection of fruit came from Mr. W. Grove, who put up 30 dishes of apples and pears in splendid condition, and some well-ripened Muscat grapes. Mr. Deacon and Mr. Smece contributed beautiful collections of apples, pears, and grapes. Mrs. Grove contributed a beautifully-finished decoration for the dinner-table, which was much and deservedly admired. Mr. Burton presented an attractive design for a garden, wrought out in sand and flowers.

SOUTH LONDON.

The exhibition by this society, at South Street, Camberwell, was fixed at a later date than others, and was the better for it, the plants being full out, and, generally speaking, in excellent condition. In the classes for plants, Mr. James Butcher took first place in the classes for 6 and 3 respectively, the best 3 anemone pompons, and in several other classes, inclusive of groups of pretty bushes in 48 and 32 sized pots. The best specimen pompon came from Mr. Bignell; it was a well-grown plant of Madame Marthe. An extra prize for specimen pompon was awarded to Mr. Maidnell.

CUT FLOWERS.—12 *large*: 1st, Mr. Tozer, who showed good samples of Princess of Wales, Lady Slade, and Rifleman. 2nd, Mr. Payne, who had good blooms of Prince of Wales and White Globe. 3rd, Mr. Pink. In the maiden class for 12 *large*, 1st, Mr. Barker, with Lady Slade, Jardin des Plantes, Empress of India, and others. In the maiden class for 6 *large*, 1st, Mr. Barker, who had fine blooms of Jardin des Plantes, Beverley, General Slade. In the class for 12, to be judged by properties only, 1st, Mr. Butcher. In the corresponding class for 6, Mr. Payne presented the best group. Mr. Lecquire presented a fine half-dozen in the class for amateurs, amongst them beautiful examples of Lady Slade, Prince of Wales, and Beverley. 2nd, Mr. Pink, with Themis, General Slade, and others. 3rd, Mr. Butcher. 4th, Mr. Hurd. 6 *anemones*: 1st, Mr. Butcher, whose blooms of Gluck and Prince of Anemones were extra fine. 2nd, Mr. Pink. 12 *bunches of pompons*: 1st, Mr. Butcher; 2nd, Mr. Head, jun. For the best bloom in the room, the winners were Messrs. Payne, Lecquire, and Tozer. A first-class certificate was awarded to Mr. Butcher for two seedling anemones of 1867.

THE TEMPLE GARDENS.

Out-door exhibitions of this favourite autumnal flower deserve the attention of all who are interested in making floriculture largely subservient to the happiness of mankind. If the chrysanthemum were adapted only for the conservatory and the exhibition room, it would be one of the most popular of popular flowers, but its out-door uses enhance its value a thousandfold; and, indeed, whatever can be made available to brighten up the ground in the dull season of November must be precious to human eyesight. The public have every year an opportunity of judging what may be done with chrysanthemums as materials for the decoration of the open garden, and though this is not one of the best seasons known to cultivators, these gardens have for a long time past been extremely gay with them.

Mr. Broome's border at the head of the garden has been and still is bright with myriads of well-grown flowers. The manner in which the border is now covered contributes greatly to the pleasure of an inspection, especially on those days when a bleak wind suggests the desirability of ignoring gardens and gardening altogether. The large incurved varieties are the especial favourites of Mr. Broome, as becomes the veteran florist. These he manages with consummate skill, and as the names are attached to the best flowers, visitors have abundant gratification. During our brief inspection, we noticed as particularly good the following: Mrs. George Rundle, White Globe, White Queen (which is the same as the Empress of India), Beverley, White Formosum, Venus, Hermine, Little Harry, this is very good, and, being compact and stiff-habited, lasts a long time; Jardin des Plantes, Yellow Formosum, Chevalier Domage, Faust, St. Patrick, Sparkler, Lady Harding, Dr. Sharpe, one of the most brilliant flowers known amongst chrysanthemums; Hereward, Cherub, Gloria Mundi, a fine yellow; Prince of Wales, General Slade, Prince Alfred, this is always good, and scarcely ever needs to be dressed for show; Ranunculus, Mr. Gladstone, Bernard Palissy, Arigena, Prince Albert, fine for colour; Progne, Nil Desperandum, &c. Mr. Broome has filled his beds with nice bushy plants of the several varieties of Cedo Nulli, a capital plan, as they all grow alike, and make a charming variety of distinct and bright colours. Mr. Broome has to furnish these beds several times in succession throughout the season, hence the present display is produced under circumstances of peculiar difficulty, and is by so much the more praiseworthy.

Mr. Dale appropriates but a small extent of space to show flowers; but in his little tented corridor he has some beautiful specimens. Here we noticed fine examples of Jardin des Plantes, Antoulli, Lady Slade, Mrs. George Rundle, Vesta, Nil Desperandum, Fleur de Marie, Hotty Barkor, a scarcely known but most valuable flower for its colour, which is a bright pink shading to a lilac.

Mr. Dale makes amends for the limited extent of his display of large flowers by truly splendid beds of pompons. These flowered rather late, but came out well. There are some brilliant beds of Salamon, Aurora Borealis, Comto Achille Vigier, and others. The composite beds, which for several years past we have described at length, are as perfect as ever, and models for imitation in any private garden where late autumnal flowers are wanted. Let us again take one bed as an example. The diameter of the bed is about 15 feet; it is planted with centro of Gerbe d'Or, a fine yellow in the way of Aigle d'Or, but holding up its flowers better; then in succession to the margin there are circles of Aurora Borealis, Mr. Murray, Miss Talfourd, Lilliputian, and Canrobert. The stiff-habited kinds, such as Florence, answer better for this kind of work than many of the varieties that are prized at exhibitions; and there are a few, such as Riquiqui, that are of no use at all, though in consequence of their fine colours they would be invaluable were they manageable.

BUCKINGHAM PALACE.

During the whole of the past month of November, the great conservatory at Buckingham Palace, Pimlico, has been gloriously gay with specimen chrysanthemums. Mr. Wynoss, Her Majesty's head gardener there, is an enthusiastic cultivator of this noble flower, and one of the few remaining

veterans who have seen its first developments of the possibilities of perfection. If we could have gathered a little company of sceptics, or, in other words, of such as "don't like chrysanthemums" amongst the practitioners of horticulture, to go round the conservatory with us on the occasion of our visit lately, we think there must have resulted a complete conviction in the mind of all that this is indeed a noble flower, when generously dealt with and judiciously exhibited. It needs judgment, certainly, in its presentation; hence badly managed shows do more harm than good; they simply disgust people with a flower which it is admitted lacks positive colour, but which by its season, variety, adaptiveness, and intrinsic beauty, merits all that can be said in its praise, whether as a subject for home decoration within doors and without, as well as for the exhibition. Mr. Wyness has grouped his plants, which are mostly tall single specimens, such as are grown for cut flowers, with leafy plants of various kinds, such as palms, ferns, camollias, huge cypripediums, citrus, and other subjects of a solid and massive character. From amidst these masses of foliage rise the grand flowers of the chrysanthemums of all colours, the many white and yellow flowers telling well in the midst of dark green foliage; in fact, the abundance of leafage brings out even the brassy, coppery, and bronzy flowers perfectly, and these are usually the least telling where *chrysanthemums only* are seen.

The greater part of Mr. Wyness's plants, some hundreds in number, have been grown out of doors in the open ground until the end of September, or later, and were then potted, staked, and grouped, and allowed to flower. The buds were of course thinned out long since, so that the average number of flowers is about half a dozen to a plant, and these are for the most part fit for show. There must have been some two to three thousand of specimen blooms in the conservatory during the present season. This brief note will prove that the growing of superb flowers may be reduced to a very simple system, and possibly many of our readers who cannot find time to attend to potted chrysanthemums in the height of summer may be induced to give this easier plan a trial. There are, first, two conditions essential to success—the ground must be thoroughly well prepared by deep digging and abundant manuring, and the plants must be put out as early in the spring as it is safe to do so.

Another matter of great importance in reference to this particular display is that fire-heat has been used freely and *without injury*. On the day of our visit the Prince of Wales was enjoying the beautiful scene, and, it may be, visitors were not unknown; therefore a comfortable warmth was an essential aid to the proper use of the display. We did not look at the thermometer, but the temperature must have been about 65°. Mr. Wyness assured us that the fire had been going steadily for some weeks past, and we therefore took particular notice of the foliage, which was fresh and green, and the colours of the flowers were pure and bright.

We forbear to enumerate the varieties that were most prominent in this splendid collection, because in all our reports, more or less, the names of varieties are predominant. But we are bound to notice a splendid seedling variety here, called *Princess Beatrice*. This is a grand incurved flower of the finest form and style of finish, and, what is of the greatest importance, the colour is a lively tint of rosy-pink. It is a glorious addition to the few good varieties of *cheerful colours*, and whoever gets possession of it will prize it. What is to become of this, one of Mr. Wyness's best seedlings, we do not know.

CORRECTIONS.—In report of Brixton Hill, given last week, Mr. Alunn (1st prize for 3 plants, &c.) should be Mr. Munn, gardener to J. Treadwell, Esq.; Mr. Battery should be Mr. Buttery; for Mr. Tilee read Mr. Filec; for Mr. Salman read Mr. Salmon. The reporter states that he copied the names from the cards with care.—At the East Tower Hamlets show, the 1st prize for 12 blooms, a silver cup, presented by Mr. R. Atkins, was awarded to Mr. W. Eickhoff.

LINDSEY HOUSES, CHELSEA.

The lovers of the Chrysanthemum may now witness some notable examples of successful training of this splendid autumnal flower, in the front gardens of several houses on the banks of the Thames, in the above-named locality. The various colours of yellow, pink, crimson, puce, bronze, white, and particoloured, of large and pompone varieties, are here so happily blended, and so neatly trained to the party-walls and palisades, as to form the most delightful and unique exhibition it has been my lot to witness in the open air, under such a simple course of culture as has here been pursued. The plants occupy narrow borders at the foot of the party-walls, which, as I happened to be passing in spring, I saw were being manured and deeply dug, the old plants being pulled to pieces, and the fragments (of large and pompone varieties) mixed, and planted close to the wall. The after-treatment seems to have consisted principally in neatly training, blending, and interlacing the branches of the various sorts, so as to thoroughly clothe and cover the walls from the ground upwards, both with healthy foliage and flowers, forming now the richest mosaic, only possible with the peculiar tints exhibited in the flowers of the chrysanthemum. Trained in the usual fashion, this plant presents a far less satisfactory appearance (with its bare stems, devoid of foliage for some distance from the ground, and huddled patches of colour), than by the mingling and blending plan above described. And those who have unsightly walls, palings, &c., in their gardens, will do well to run down and take a lesson on chrysanthemum training from these examples. Steamboats, from all the piers, will land visitors at Battersea Bridge, within one minute's walk of the spot.

November 21st.

A PARROT STORY.—"You see," said the old darkey, "dis parrot belonged to a baker in Richmond. Now each baker is 'lowed to make a certain number ob loaves ob bread every day, and no more, 'cause if they do they will be serving out stale bread to the customers. Well, dis baker had baked more than his share one day, an' hid de surplus under de counter. De parrot was hanging in his cage and seed it all. Bimeby in comes de inspector an' finds ob bread alright, an' is goin' out again satisfied, when de parrot cocks his eye at him and sings out, 'Dere's more bread under de counter!' So de inspector grabs it, 'cording to law, and carries it off. Well den, de baker goes to de parrot werry mad, an' takes him by de head, and fatches him a twitch or two an' flings him in de gutter for dead, 'longside a pig just dead ob de measles. Bimeby de parrot begins to crawl about, his feathers sticking out, an' his head lopped on one side, an' den stops an' looks at de pig werry pitiful, an' ses, 'Did you say anything about de bread?'"—*New York Sun*.

THE GREAT VINE AT THE VICEREGAL GARDENS, DUBLIN.

The Finchley vine was planted in 1855, and it now fills a span-roof house, 89 feet long by 16 feet wide. Mr. Thomson, in the last edition of his invaluable "Treatise on the Vine," tells us that he "saw it in 1864, when it had a full crop of excellent grapes, weighing 476 lbs.; in 1865 it bore 400 lbs. of grapes; in 1866, 300 bunches, some of them weighing 5 lbs.! It took seven years to furnish the house with bearing wood." About the same time as the Finchley vine was planted, one of the compartments of the fine curvilinear range in the Viceregal Gardens, which had been used as a fish-house, was diverted from the latter to another purpose, and cleared of the figs. The length was about 70 feet, the breadth then about 16 feet, or something more. At one end a large plant of heliotrope grew for years, its sweet-scented flowers being in demand at the Lodge. Growing with and among the heliotrope, a vine-shoot used persistently to come up year after year from a stool, or, perhaps, a vine that had by chance been stuck there. Be this as it may, Mr. Smith took pity on the struggler, and resolved to give it a chance. He led the rod up the end the first year. From this leading stem another season he trained four laterals longitudinally at intervals of about four feet towards the opposite end. A short time sufficed for these laterals, closely spurred, to extend the 70 feet, and carry splendid crops of highly-finished grapes. It was resolved to widen this and other portions of the range by removing the wall back some eight feet, and forming a hip or half-span, thus making the width about 24 feet. This afforded room for another longitudinal rod under the ridge, and from this short rods are taken at right angles down the hip towards the back wall. It is some five or more years since we first drew attention to this magnificent vine, and the splendid crop it then carried. Since that it has year after year been a source of wonder and admiration to all who saw it, yielding annually somewhere about a quarter of a ton weight of large bunches and highly-finished grapes.

This year it was a picture, the bunches being beautifully coloured, more especially towards the upper portion of the rods. The weight of marketable grapes was accurately kept, the result being 6 cwt. 1 qr., which, at 2s. per pound—a low figure, considering the quality—would bring £70. The crop was not ripe till September (very little fire-heat having been given), when grapes are abundant, and do not bring more than the above figure. If forced a little, and in a little earlier, the crop would bring double £70.

One of the principal, and perhaps the only valid, objection to a single vine is that which holds as regards the one-boiler system. If anything goes wrong there is a hitch, a blank. This, however, is easily obviated by having a second vine planted at the opposite end, and letting the rods alternate. Mr. Smith, with this view, we perceive, has planted a white grape at the opposite point. When this latter extends, as the other has done, the effect of the pendent lines of luscious clusters, black and amber alternating, will be very beautiful to look at. We trust this splendid example of the extension system, and of our good friend Mr. Smith's skill as a first-class grape grower, will long maintain its vigour and productiveness, and continue to be one of our horticultural wonders, and the pride of the Viceregal Gardens.—*Irish Farmers' Gazette*.

REMARKS ON THE PRACTICE OF UNNAILING WALL TREES.

Many of our profession permit themselves in their practice to be guided by traditional rules, regarding any diverging from them as savouring of *theory*. I very much regret that the use of the word "theory" is generally but ill understood by my brother gardeners. It is not an uncommon occurrence to meet with many in our craft who are anxious to impress us with what they consider a very serious fact, which is, that their practice is quite divested of anything that has the remotest connexion with theory, while at the same time they are daily in their practice indulging in speculative flights, and so illustrating all that they wish to be understood as condemning. Are we not often cherishing the thought that we are the sole possessors of some particular method of culture which others have yet to discover? Now the conception of that idea in the first instance was perhaps hypothetical, and required working out to elevate it into a theory. But regard it in whatever other sense you may, it amounts to this much, that having ascertained its value you have reduced it to practice, and theory is nothing more than the reason for the practice—the rationale of the facts on which practice is founded. This latter remark applies to my subject—the treatment of peach and nectarine trees when planted against garden walls. Many very excellent gardeners still persist in adopting a very old plan at this particular season, —that of unailing the principal portion of the shoots or branches. Does this practice benefit the tree, or, otherwise, is it necessary for the promotion of health and their fruitful qualities? I contend that it is not actually essential for the fulfilment of these requirements, that we should annually resort to the system of stripping them of the major portion of their shreds and nails. My experience has led me to test both modes. Let it be understood that I am speaking of those that are of mature growth, and not young fast-growing trees, whose branches have to be retrained annually, so as to fill up vacant spaces. Let us consider both sides of the question; first, we relate the arguments mostly advanced by those in favour of unailing the branches. They say by removing and cleansing all the old shreds, and adding new where required, that we are performing a very useful work—that of destroying a quantity of insects that as yet are in embryo, they being secreted in the shreds and crevices of the wall, and that by loosening the shoots we admit the elements to perform their work of cleansing the latter. Further, it is argued that it will retard their blooming season, thus enabling us with more certainty to secure a crop of fruit, by escaping the evils which late severe spring frosts inflict on vegetation. I will endeavour now to refute these propositions, basing my argument in the first instance on the importance of saving time by abstaining from useless labour. The majority of gardeners are not burdened with superfluous assistance, and perhaps there is no operation that consumes so much time in the spring as the nailing and training of wall trees; and more so where the walls are of any great extent. In the most favourable weather it is a tedious employment, and it frequently has to be done in very cold dull weather, because the season is so far advanced as to require the completion of the work.

The practice which I now advocate, and have pursued for the past several years with success, has been to afford more than ordinary attention to the training and disbudbing of the shoots during the summer months. The latter work is generally performed very quickly, and thus, instead of nails and shreds, twigs are employed, which are fastened crossways or otherwise, so as to retain in position a number of shoots at once, and thus the labour is

reduced which would have to be necessarily expended, if the individual shoots required for next season were to be permanently trained and nailed. I now ask, why should the tree be allowed to support for several months wood that must be considered as nothing more than surplus stock? And does not the crowding of such a quantity of useless wood tend to encourage the breeding of insects? I contend that by carefully attending to the requirements of the trees for the succeeding year, we aid in preserving their strength, and afford those shoots that remain the advantages which light and air confer in maturing their growth. Of course I admit that the trees will require the usual survey in the spring or winter, but their useless wood can be removed without altering their symmetry, or unnauling the whole of the branches. Some of the shreds will also fit tightly; these will have to be loosened.

Not a few of the drawbacks to which wall-trees are subject may be often traced to the lack of due attention during the summer months. This does not arise from wilful neglect, but from the pressure of other work which so divides our attention; yet, if we are anxious to preserve them in health, we must bestow a little extra time at that particular season in attending to their wants. One of the great evils of unnauling is that, for the purpose of getting quickly over the job, a great deal of hacking and cutting away of the wood is resorted to, so as to reduce the labour of nailing. If we want an example of the benefit which accrues from the system now advocated, we have only to take the chrysanthemum and many other similar plants, which have to attain quantity and quality within a given time. The growers of them always remove all superfluous wood and laterals as they present themselves, so as to allow the energies of the plant to be devoted wholly to the flowering wood.

Surely the practice of annually unnauling the whole of the lesser-sized shoots and branches, must tend to increase the means of secretion for insects caused by the vacant holes which the withdrawn nails have left! To avoid some of the evils which nails create, I have known the proprietors of gardens to have strong wires perpendicularly fixed at equal distances; to these the trees were trained by tying, &c. I think it is unwise to endeavour by artificial means to seek at any time to check their blooming season, as it must to some extent cripple the maturity of the flower, for the more freely the flower develops itself the finer will be the fruit. The greatest danger we have to guard against in the shape of frost is when the fruit is just emerging into its first stage of swelling; then it is we must be on the alert to shelter them from the effects of late spring frosts. Possibly damp does more harm than frost to all kinds of fruit-trees upon coming into flower, and hence the value of a good coping to a fruit-wall. In concluding these fragmentary remarks, let me remind my readers that we cannot supply the roots of the wall-trees with too much moisture during hot weather, as in the absence of such, red-spider is sure to spread among the foliage, and often it attains such a mastery as to prevent the perfect ripening of the wood. JON. F. McELROY.

HOOLEY HALL, THE SEAT OF J. C. PICKERSGILL-CUNLIFFE, ESQ.

This magnificent horticultural emporium is very prettily situated on the main line of the London and Brighton Railway, above the banks of which the mass of glass resembles a crystal town, in the midst of which appears the noble mansion, giving to the whole a fine and proportionate effect. The liberal and enthusiastic owner may justly be proud of the very excellent and well-constructed plant-houses which range here at every angle, subservient to the requirements of all classes of plants and fruits, also of the very fine condition in which every occupant is now in, to the great credit of the very able gardener, Mr. P. Mundell, who, during his sojourn at Hooley, has done much to improve the state of all under his charge. It must be a source of great satisfaction to his employer to see the skilful manner in which plants from every clime are handled. Here may be seen specimens of the extraordinary and curious lattice-leaved plant, *Owivandra fenestralis*, luxuriating with all possible vigour, and every ramification of its strange skeleton leaves perfect in structure, and all as happy as if growing in the steaming pools of that little known country, Madagascar, to which alone it is indigenous. In close proximity to this humble but rare aquatic, the magnificent *Musa sapientum* rears its majestic head some thirty-five feet high, and bearing a ponderous spike of huge golden fruit, colouring and looking as luscious as if it were revelling in its native wilds. Rivalling this glorious tropical giant, were some luxuriant specimens of Mandarin oranges, with foliage as green as spring grass, and bearing a crop of luscious fruit, which for excellence cannot be surpassed even in the celestial world, where climatic and other influences have the effect of rendering this fruit as common as cider apples in the West of England. Having glanced at these things, one is rapidly transported into a complete labyrinth of plants from almost every region of the globe. Orchids of the most curious types, both from the eastern and the western hemispheres. Ferns with rich waving fronds, showing the wealth of the world in this respect from Great Britain to Australasia. The beautiful Chilean climber, *Lapageria rosea*, and its beautiful variety *L. rosea alba*, are here in their glory, growing and flowering like European hops; and from the roof of this cool house hung myriads of bright crimson flowers of the showy *Tuesonia Van Volxemi*, the flowers of which are upwards of 8 inches long, suspended by thin foot-stalks of extravagant length. When trained, as I saw it here, on a roof at an angle of about 15°, the flowers of this superb climber are shown off to advantage, and prove this to be, when thus managed, the finest species of its numerous race. The *Ananassa*, or Pine of Jamaica, in its variegated form, was bearing a fine fruit, and showed the watchful skill of the manipulator in the robust health of this rare plant. But to do justice to this extensive collection, I will enumerate a few of those plants which here are the very acme of perfection. I will commence with the long span-roofed stove, upon the roof of which hung suspended fine panicles of flowers of the pretty *Pissiflora Kermesina*, *P. princeps*, most elegant; *Ipomoea Horsfallii*, *Bolatus paniculatus*, *Bougainvillea spectabilis*, and *Allamanda glabra* in variety, *Stephanotis floribunda*, &c. In the natural beds beneath were stately and well-grown specimens of *Crotan angustifolius*, being particularly long foliaged and well coloured; *Maranta Warscewiczii*, a new species from South America; also *M. Vanden-Hoeckii*, *Regalis*, &c. &c.; *Sansiveria Javanica*, *Coccoloba platycentra*; and among this group was a beautiful Palm, *Araca rubra*, one of the finest members of this noble family; *Cyathus circinalis*, the new *Dracena Veitchii*, *D. ferrea striata*, and a host of other rare and beautiful fine-foliaged plants. In the midst of this imposing group was a tree of beautiful proportions of *Stercubia fatida*, turned out and growing from the unheated border.

Adjoining this fine stove is the specimen Musa house, having the whole family of the Bananas planted out, and reminding one of a tropical forest,

wherein may be seen all those useful medicinal plants which add so much to our physical comfort, and which afford such a staple part of our foreign commerce. Intermingling with the tall gaunt stems of the *Musae*, were the tortuous and flexible branches of all the *Piceae* family, the stately *Myristica moschata* (nutmeg), the *Theobroma cacao* (cocoa), also the cocoa-nut palm, the allspice, cinnamon, black pepper, date palm, sago palm, &c. &c. On the sides of this stately house was a fine plant in full fruit of *Pissiflora quadrangularis*, also *Quisqualis indica*, reaching the top, and throwing out immense corymbs of scarlet blossoms. Here also was an *Allamanda Schottii* upwards of 20 feet high, with scarcely a bloom showing, while a plant of the true *A. Hendersonii*, not as many inches in height, was loaded with its yellow and maroon flowers. This species is a perpetual flowerer, and it is no difficulty to have it in flower for nine months successively. Unfortunately much confusion has been brought about in reference to this grand plant by Schottii being sent out for it, by those of the trade who erroneously supposed at first that the two were identical, but in which there is no resemblance whatever, except that they are of the same genus.

Attached to this house is what is termed the "East Vinery," in which are fine rods of beautiful, large, solid, short-jointed, and well-ripened wood, and on the back wall all the best figs in excellent bearing condition. Leading from this is a greenhouse, well filled with miscellaneous hard-wooded and hair-rooted plants, some flowering, others growing, and all in the best possible condition, and looking very gay. The division of this range is an intermediate section filled with plants chiefly indigenous to Van Diemen's Land and Australia (South). Emerging from this, the *Nymphaea* (water lily) house attracts attention. It is filled with all the choicest and rarest aquatic plants, associated with which are fine specimens of *Alocasias*, especially of *Veitchii*, *Zebrina*, *Lowii*, &c., &c.; also *Anthuriums*, *Crotons*, *Monstera* &c., and an admirable specimen of the sweet lemon-grass, *Andropogon schenanthus*; *Begonias*, and other charming fine-foliaged plants, are distributed about this interesting house, and myriads of rare plants dotted about the rocky sides of the water-tank, over which is suspended the beautiful Amazonian Cissus, and other aquatic climbers, whose roots, after ramifying through every moist crevice, reach to the water at last, and appear to live entirely from this source. All this fine rich foliage rambling away in wild confusion, gives this house a most interesting and charming appearance. It was in this house I noticed the mad-growing *Aristolochia ornithocephalum*, and *Cymbifera Thunbergia Laurifolia*, a host of climbing ferns, &c., &c.

Next in order was the Muscat house, with fruit beautifully ripened, still hanging. Fine bold berries, amber in colour and bunches well shouldered, were the chief characteristics of the crop; while beneath them, in the same house, were fine peaches and nectarines in pots, which had borne splendid crops, averaging five dozen on each, and looking as if they would give double that crop next season. In the pine stove were a lot of clean and healthy plants in different fruiting stages; the Queens especially had done good service. The lightest which Mr. Mundell had placed in the scales turned 4 lbs., while the heaviest was upwards of 7 lbs., and the whole indicated a masterly hand in their management. Amongst them were some remarkably fine winter cucumbers, which Mr. Mundell always prefers to grow in pots for winter use. His great theme is at all times to have full power over the roots, and his practice in this particular is everywhere traceable in the luxuriant state of his plants. Round the sides of this house is a reserve of winter-flowering plants, such as *Justicia*, *Poinsettias*, which are here grown as bushes, *Eranthemums*, *Libonia*, &c., &c.

Hard by this interesting house is the span-roofed orchid house, well filled with named and unnamed species. Among the former was observed, in good order, *Lelia Perrinii*, *L. superbium*, *L. purpurata*, making beautiful pseudo-bulbs, *Cattleya crispata*, *C. Mossiae*, and varieties, *Vandas*, *Epidendrum*, *Aerides*, *Calanthes*, *Dendrobium*, *Stanhopeas*, and other types of this interesting order. Among the unnamed species was one somewhat resembling *Phalaenopsis Schilleriana*, but having the laminae shorter, the mid-rib curved, and the whole surface of the leaf irregularly blotched with maroon. This, with many other very interesting species, especially a few after the type of *Sophranitis*, I found had been introduced from Central America by Mr. Bowman, who is exploring that part of the world in search of botanical novelties for Mr. Cunliffe. Through the same source this lover of horticulture has obtained many valuable bulbs of the liliaceous order, also some interesting *Physurus*. In this house was a beautiful specimen of that rarest of rare plants, the silver palm, *Calamus dealbata*, about which I shall have something more to say in future. Mr. Mundell in this house made a rapid stride in both ornamenting and utilizing the spaces beneath the stages. Rockwork has been erected, and the interstices filled with ferns, lycopods, &c., producing a pleasing effect, and subduing the harsh emptiness which all houses present which have staging on their sides and the spaces vacant beneath. In a new house recently planted with vines, all was ready for starting and cutting in March next—fine rods, clean and well ripened. Through the centre of this house is a water-tank for evaporation, and part confined for propagation purposes.

A range of peach houses, with two divisions, next commands attention. The wood of the trees is well ripened and set for the ensuing year's crop. These trees were nicely balanced with bearing wood, and showed unmistakable symptoms of good management; beneath were some admirable pyramidal specimen azaleas, and a few New Holland plants, all having been well baked in the autumn sun, and housed with a glow of health that is seldom seen in this class of plants during the late autumn months. In one corner of this house was the dormant plant of *Lilium agatum* which appeared upon our horticultural tables at Kensington and Regent's Park, in a 16-inch pot, the stem 8 feet high, and 15 blooms, each 14 inches in diameter, all expanded at the same time. This feature alone will suffice to illustrate Mr. Mundell's belief in the policy of artificial feeding of all members of the vegetable kingdom.

In the late vinery some alterations have this season been made, and young canes of Lady Downes, Alicante, &c., &c., have been planted. The house is now occupied with soft plants for greenhouse winter decoration; a fine range of pits is devoted to primulas, cinerarias, &c. Near here were upwards of 2,000 strawberries in pots, bearing fine, round, bold, plump, well-ripened crowns, and which promise well to yield abundance of fruit. Emerging from the forcing garden, we find ourselves in the midst of confusion, the old mansion being partially pulled down and rebuilt; new bowling green, croquet grounds, and pleasure grounds, are being made, and when completed will certainly much better correspond with these fine gardens and magnificent piles of glass. The whole of the plant-houses are heated upon the one-boiler system, which has recently been entirely remodelled, and the system much simplified and made much more secure. Three of Weeks's tubular boilers, No. 6, and one of No. 5, have been placed side by side with a spacious chamber at the back, in order that, should anything happen to either,

they can be taken out, examined or rectified, without interfering with the work of the remaining two. They all possess separate valves in the flows and returns, and each boiler can be worked uniformly with or entirely independent of each other. The system is the most complete I have yet met with, and tends to prove how ardent an admirer of nature and her vegetable beauties must be the proprietor of this princely place. The great attention, the solicitous care, and the liberal spirit which actuates him to meet the wants and requirements of the vast family of plants he has in his possession testify that love is the mainspring of his actions. May he live long to enjoy that which nature has ordained for the pleasure and recreation of man!

Epsom, Surrey.

J. R. T.

CONSTRUCTING A VINERY.—No. IV.

BEST FORMS OF HOUSES AND MODES OF VENTILATION.

For all early vinerics, whether large or small, no less an angle than forty-five degrees will prove satisfactory, and even fifty is not too much, especially in a low or shaded situation, as it is at all times desirable to secure as much of the sun's influence as the season of year will give us. An angle of forty will serve for those vines that are allowed to break naturally, as by the time they commence to grow the sun gets sufficiently high in the heavens to allow it to act with such force upon the house as will suffice for the free growth of the vines.

As regards the construction of the roof of the house, there is none to surpass that which allows plenty of air being given at the apex; and the old-fashioned sliding lights are not to be despised. But Messrs. Weeks and Co. have made a great improvement on these, by an ingenious piece of machinery which lifts simultaneously every top light. Air is thus given—little or much as it may be required—by simply turning a winch a few feet from the floor of the house. This simple although eminently ingenious piece of work does not put the lights out of their place further than raising them. Therefore, no rain can find its way into the house, which makes this principle of air-giving superior to the old sliding lights. The reader will find some description of this invention in my notes from Hawkhurst, Kent, where I saw it in work. Next to this invention, I prefer the sliding lights as offering the least obstruction to the escape of heated air. Those with fixed roofs, with ventilators in the back wall, are the next to be recommended, although they are not so well adapted for very early forcing, as there is nothing to check the ingress of cold air, like those houses which have a parapet carried above them, and the lights to raise or slide.

The worst of all descriptions of houses which I have dealt with for vinerics are those with roof ventilation,—I am not speaking of those patented within the last three or four years, but those of older date,—and, so far as my experience guides me, I cannot find one redeeming quality in them, as adapted for growing grapes with any degree of safety. It is quite true that good grapes are grown in them by some cultivators, but the general public know but little of the anxiety and the cares attending their production. I need not here give my special reasons for disliking them, but I may remark that I will not again risk my reputation in any place where I am required to force early grapes in houses with roof ventilation; and in this determination I do not stand alone.

Coming now to the question of front ventilation, I have always found it advisable to provide it either in the form of a sash or boarded ventilator. For a low-pitched house, a front sash is the best, either to open outwards or to swing on a pivot at both ends. Wires must be provided on which to train the vines; these should go lengthways the house, and be at least fourteen inches from the glass, and about ten inches between each two wires.

PLANTING THE VINES.

Vines may be planted with safety early in the autumn or the spring, or indeed throughout the summer, but winter planting in outside borders should be avoided, unless the roots are protected from wet and cold. I have previously briefly stated in these pages how well I succeeded with a house of vines planted early in the autumn, a few years ago—how by watering them with tepid water, and immediately covering up the border to confine the heat and to carry off the rain, cutting them down in mid-winter, and applying some hot fermenting material upon the top of the border in the spring to excite root action. Increased experience convinces me that with proper care this plan is preferable to planting dormant vines in spring; nevertheless, many prefer the latter method. So, I would say to all those contemplating the planting of vinerics next spring, secure your plants at once, cut them down to within seven or eight buds of the crown, cutting out all the eyes except the two top ones, and then stand them by in some cool house until the end of next March, if for outside borders; but if for inside, let the planting take place a month earlier. At the time of planting shake off all the

soil from the roots, and spread them out evenly over the soil not more than six inches under the surface.

Next to autumn planting is early summer planting: this is not yet practised by many, owing to its not being rightly understood. In many instances it is a very valuable practice, as it will be in my own case next spring, when, if I am spared, I shall work it out as follows: Having two new vinerics to plant—one in an inside border, and the other outside—I have obtained a sufficient number of plants to plant them both. The Black Hamburg house, with its inside border will be planted early in the now year; for the other house I have different varieties which I was anxious to secure. From these fruiting plants just brought in, I shall take three or four eyes from the points of each to strike in about a month's time. These eyes will be at once plunged in a bottom heat of about 80°, with a top temperature of 65°. With this treatment the buds will soon start into active growth; they will be repeatedly shifted, as they fill the pots full of roots, until the end of next April, at which time they will have attained a height of three or four feet or more. They will then be gradually hardened off in a greenhouse temperature, and be finally planted in the border about the first week in June. Thus I shall secure a stock of young plants for my house, while those which most people would have planted I shall have to fruit in pots in the same house, securing not only the plants, but a crop of fruit the same year.

Now, if any one asks how will the young planted canes succeed, let me say equal to, if not better than, those older plants would do, had I put them out instead of forcing them. When these young canes are planted with care in a well-prepared border, they seldom make a regular stand after planting; their roots are young and active, and by previously warming some nice fine soil to place round them, they at once take hold of it, so that there is scarcely ever any perceptible check upon their growth. I do not advocate this plan because I adopt it now under a force of circumstances, but because I know better results would many times be obtained than where weakly plants are put out in spring. It is nevertheless good for us all that we should sometimes be put in a strait, as it serves to bring out many useful lessons, for we can ill spare the loss of a whole house of grapes. But as the old vines removed from the house these young ones will occupy were past recovery, there was no alternative but to grub them up, and as stocking it again for one season with purchased plants of fruiting vines would be an expensive job, I am compelled to do my best towards preventing the loss of a crop, and at the same time secure a stock of plants of the same varieties for the permanent vines.

I append here a short list of varieties of grapes to meet the wishes of a correspondent, G. H. Sherman, of Colchester, but from which any of my readers may select with perfect safety.

For an early house.—The Frankenthal Hamburg, Black Prince, Black Hamburg, and Buckland Sweetwater.

For an intermediate house.—Pope's Hamburg, the Champion Hamburg, the White Frontignan, Trentham Black, Foster's Seedling.

For a late house.—Muscat of Alexandria, Lady Downe's Seedling, West's St. Peter's, Mrs. Pince's Black Muscat.

To these may be added the Canon Hall Muscat, a noble grape, but only adapted when it can be grown in a house by itself with a heated border, and to receive a temperature of 10° more heat than any other variety will bear when setting its fruit.

J. C. CLARKE.

SLAUGHTERING OF CATTLE.—*Galignani* states: "A series of curious experiments took place a day or two ago at the new slaughter-houses at La Villette, with a view to try whether oxen might not be spared the frightful tortures it is supposed they endure on being felled with sledge-hammers. It was believed that enervation might produce the desired effect, and this opinion was founded on the decision of physiologists, who affirm that the section of the spine will strike the animal down as if by lightning. The experiments, however, have not corroborated this opinion; on the contrary, it has been found that, although by enervation the ox is killed more rapidly, its sufferings are much greater, since it remains alive for more than fifteen minutes, and that it has not only the feeling of pain, but even the strength to keep back its blood when the veins were opened. Other experiments were made on sheep and calves: their heads were cut off, instead of merely cutting the spine, when curious signs of vitality were observed in the head. In one case the latter lost two ounces and a half of blood in six minutes. During the first minute all the muscles of the face and neck were violently convulsed; during the two following minutes the convulsions assumed another character; the tongue protruded from the mouth, which opened and shut as if the animal were alive, and the nostrils also expanded and contracted regularly. These convulsions increased when the tongue and nostrils were pricked with a pin. On putting the hand against the mouth and nostrils, the air was felt to go in and out as the head breathed. If a finger was held near the eye at a distance of two centimètres, the eyelids would shut, and then open again. This lasted a minute and a half; after which the eyelid would only close when touched; after the fourth minute it became necessary to irritate the conjunctiva in order to obtain a similar effect, and after the sixth minute all motion ceased."

ON SUPPORTS FOR STANDARD ROSES.

A great difficulty for the rose-grower is to find proper supports for his standards. A stako driven into the ground

beside each rose, as generally used, is neither lasting, efficient, nor ornamental. If the roses are in line, it is much better to

have a wire extended for them all, which sways gently with the wind, and is capable of supporting them through the greatest storms; and as I have found it to succeed, and also, as I believe, have discovered the best manner of straining a wire for the purpose, I beg to send you the result of my experience. I. T.

STRAW FOR SHELTER.

The importance of shelter for stock in winter has been frequently discussed and strongly enforced in this journal—and it is to be presumed that every farmer will admit the principle—but some plead in extenuation of their negligence in this matter the impossibility, on account of their limited means, of putting up sufficient shelter for the comfort of animals under their charge. But this is, indeed, a very poor excuse; for where other materials are wanting, or where money and labour are scarce, most comfortable housing can be procured for stock of all kinds by an appropriate use of straw. In countries where timber is scarce, as on the prairies of Illinois, we have frequently seen the most warm and thoroughly efficient shelter secured by straw “fixings” even of the rudest kind. In these regions this is, indeed, the only abundant material for the purpose. Shelters for all domestic ani-

Fig. 1.

mals are constructed of it. A few poles form a roof-support, and the straw is piled about and upon them. On the sides of the shed the straw is either simply a trodden-down heap, trimmed with a hay-knife on the inside, or it is piled against rails. These are very warm sheds (see fig. 1), but they wet through, leak, and the straw rots, and must be removed after a short time.

Instead of these rude and primitive structures, much better sheds might be built, using the same materials. Much of the tall stubble, cut close to the ground, is long enough to make most excellent and durable thatch, if well put on. A few bundles of wheat might be thrashed out by hand and the straw saved, or even the machine-thrashed straw might be used and answer tolerably well, if a sharp pitch be given to the roof. Thatching is understood by many immigrants, and the principles upon which good work

Fig. 2.

depend are so simple, that where beauty is not demanded, any handy man will make a tight roof after a little experience. There are several methods of using straw to form the sides or walls of these stables. A convenient way is to set upright poles, about eight inches apart, and draw wisps of straw round each, so that both ends of each wisp shall be outside. It is best to lay these in horizontal courses, and beat down each course as it is laid, keeping it uniform and tight. As the filling-in with straw progresses, there may be a split pole woven in once in three feet or so, to hold the uprights in place. The straw is finally to be raked down on the outside so as to shed rain well. This makes a tight, warm, and lasting wall. The inner side is quite even, and it may be sprinkled with mud if there is danger of the animals pulling out the straw to eat. (See fig. 2.)

The accompanying illustrations, and the directions for construction, are taken from the *American Agriculturist*, to which able journal we are also indebted for the following account of other uses of straw in the same coun-

nexion. We would here, in passing, urge on all parties the importance of not deferring the necessary work of providing shelter until the severe weather has set in, and enforced the leisure to devote to the matter. A merciful farmer, or even one who has a wise regard for his own pecuniary interests, will make the opportunity, and secure the time while the weather is yet mild and favourable, so that when winter commences his stock will at once derive the protection and comfort they need, without having been previously exposed to, perhaps, some of the severest cold of the whole season.

STRAW DOORS AND SHUTTERS.

It is a great convenience where lumber is scarce to be able to make expeditiously a good door or shutter of any kind. Constructed of straw, a door may be strong, light, and tight. Tie or wire together a frame of round sticks, braced or stayed by cross-pieces to give requisite strength. (Fig. 3).

Fig. 3.

Fig. 4.

This frame should fit loosely in the window or door-place, and one of the upright pieces should be strong enough to hang the door by. Then wind a straw-rope of 1½ to 2 inches in diameter around the longest way, so as to cover the frame. Next, weave a tighter-wound straw-rope back and forth, plaiting the whole in a single mat. (Fig. 4). The strands on each side of the frame may be plaited separately, forming thus a double thickness of the straw-mat. We have seen affairs made in this way by the soldiers, and

Fig. 5.

stuffed with straw as the weaving progressed, and when done they made very good beds.

Straw-rope is made by twisting damp straw. Sprinkle a heap of straw the night before. All farmers should possess a set of centre-bits and stock. Take a large centre-bit and attach a stout wire hook to it, and place it in the bit-stock. Where the bit-stock is wanting, contrive some substitute. Two persons are required; one twists a loop of straw into the hook (fig. 5), and walks backward, turning from left to right—the other remains at the straw-

Fig. 6.

heap and feeds fresh straw to the lengthening rope. A sufficient length being attained, the rope is fastened upon a fence, or between poles or trees, until dry, when it will not untwist.

In a subsequent number of the same journal, a Scotch correspondent sent a drawing of a simple contrivance for twisting straw, in common use both in Scotland and England. The last illustration (fig. 6) sufficiently explains this home-made implement, which almost any farmer's boy will be able to construct.—*Canada Farmer*.

NOTES ON BEDDERS.

I beg briefly to reply to the interesting communication of Mr. J. B. Saunders on Bedders. I find from his observations that he occasionally visits the metropolis. I do not know whether he visited Hyde Park during the flowering season; if so, he would have seen the *Iresine Herbsti* in full perfection, forming one of the lines of ribbon border parallel with Park Lane. The secret of the successful treatment of this plant at Hyde Park was in inducing it constantly to be reproducing young growth, by pinching or stopping the shoots; such has been my practice during the past season.

As regards the Coleus and its varieties, I would only say that we are so attached to *Verschaffeltii*, that as a general rule the qualities of the other varieties have not been sufficiently tried as bedders to condemn them as in any way inferior to the established favourite. *C. marmorata* has yet to be put to a more extended trial before we can pronounce it as lacking the striking effect of *C. Verschaffeltii*; besides, we are seeking for variety. If Mr. Saunders wishes to see *C. Gibsonii* well done, he must visit Battersea Park during the season. The stock of *C. Veitchii* as yet has not spread itself so far and wide as to justify us in saying it is unworthy of a place by the side of its older rival.

The *Golden Variegated Balm*.—I did not recommend this as a bedder, but as an edging or line to a ribbon border, and I am somewhat convinced from my own practice, and what I have observed, that if the instruction contained in my notes of September 28th are strictly complied with in the annual propagating of the plants, and also the constant trimming of the shoots after they are planted, it will succeed. Thus treated, I have seen it preserve its true character till quite the close of the season. I remember a few years since visiting the garden of —Dobree, Esq., at Walthamstow, where I saw in

he month of September two edgings of this variety, forming the front lines of a broad but very effective ribbon border on each side of a long walk, and I was particularly struck with the correct character of the variegation; and the same practice as now recommended by me was adopted by the then respected gardener, Mr. Holloway. It may be that a bad variety of this plant is in cultivation. I know that frequently, when two people are discussing the merits of what they suppose to be the same thing, there is a mistake to the extent that each refers to a different object, and in that case the discussion has no practical value. No doubt our Editor can tell us if there are two distinct varieties of garden balm, as through him it was first distributed, and he has, I believe, some of the original stock still in his experimental garden.

Cerastium Biebersteinii.—In my remarks on this plant, I did not intend them to apply to the exclusion of *C. tomentosum* from our list of useful silvery edging plants (which Mr. Saunders will find on perusing my note). I should have been better understood had I have said, this variety superseded the well known *C. tomentosum* in being more erect and robust in its growth; and I intended in my observations to convey the latter meaning; but the mere omission of a word entirely alters the sentence. However, my opinion is unaltered in regard to its character: for a level surface *C. tomentosum* would have the preference, but for the front line of a bank or slope the former would be my choice, on account of its constitution.

In closing this reply, allow me to thank Mr. Saunders for his practical contributions, with a wish that many other persons interested in plants would through these pages boldly assert their opinion, though it be in contradiction to our own; it is by such interchanges of ideas that we arrive at truth, which is not and never will be one-sided. JNO. F. McELROY.

THE NEW ROSES OF 1867.

I have noticed that one of your numerous readers has been so kind as to give us rosarians all the information in his power about the new Roses of 1867; and also that he earnestly requests other rosarians to follow his example. In giving my quota of information, may I respectfully request others to do the same. About April last the following new Roses came here, viz., Alba carnea, Annie Wood, Antoine Ducher, Charles Verdier, Comte Litta, Comtesse Turenne, Horace Vernet, Jules Calot, Madame Anna Bugnet, Monsieur Noman, Madame George Paul, Madame Rival, Monsieur Thiers, Monsieur Plaisançon, Rose Perfection, Napoleon III., Thorin, and François Treyve. Such was my selection in the lottery-bag of Roses. In giving a description of the few that bloomed with me, it must be borne in mind that my residence is in the north of England, not very far from the county of Durham; consequently many roses which bloom well, and are very beautiful in the south of England, are almost worthless here. All roses to suit the northern counties should be of vigorous growth; the flowers should have coriaceous or thick leathery petals. Roses with thin petals rarely open here in autumn. I could this day, November 20th, cut a basketful of roses of the varieties having thick petals, such as Sénateur Vaisse, Gloire de Dijon, Charles Lefebvre, Alphonse Belin, and many others. But to the new Roses.

The following memoranda were made in a book at the time each rose bloomed:—

Comte Litta.—Bloomed in August, on a very small weak plant, which was cut up in May for propagation; colour very rich and beautiful, like Prince Camille de Rohau and Souvenir de William Wood; bloom medium-sized or small; petals large, thick, and velvety, imbricated, in form something like Fisher Holmes; colour velvety maroon; of free growth and handsome foliage; will be a pretty garden rose.

Antoine Ducher.—Bloomed 23rd August; colour very bright, a shade darker than Duchesse de Morny; flowers large, very double high centre, imbricated like Chabriland; outer petals shaded glaucous white; very highly scented; a magnificent rose.

Jules Calot.—Bloomed August 24th; colour a very deep rose, or light crimson, or reddish carmine; very large and very double, circular; form in the way of Madame Vidot; highly scented; a magnificent rose.

This rose and Antoine Ducher can be safely recommended.

Madame Anna Bugnet.—Colour very pale lilac rose, tinted white; large and very full, perfectly imbricated; famous grower, much scented; to give a description of colour, I may say it is something in the way of Alphonse de Lamartine. I think this will be a good rose for exhibition; it was highly recommended to me twelve months ago by a rosarian friend who saw it in Paris.

Napoleon III.—All that I can say about this rose is that it is a good grower, with beautiful foliage. I saw a bud in October, but it did not open freely. Colour of the petals dark crimson shaded purple or maroon. I do not like the shape of the bud it is long and pointed.

This rose appears to me to be nothing more than a son of General Jacqueminot clothed in a deeper shade of crimson than the parent. It may turn out a showy variety for the garden: it certainly does not come up to the description given by Eugène Verdier, and has already led to great disappointment.

Rose Perfection.—This rose I can honestly recommend. The plant is of vigorous growth, form of the flower beautifully imbricated, high centre, shape of a good Chabriland; extra large, $4\frac{1}{2}$ inches diameter, very full, abundance of stuff in it; petals large, thick, and smooth; the colour is a very rich deep rose, almost approaching to light crimson, back part of the petals a little silvery; highly scented; one of the right sort; bloomed November 12th, under a south wall, and opened freely. I have given this rose a high character, but have said nothing more than it merits.

Madame Rival.—I only saw a large bud of this variety, which had a close resemblance to Sœur des Anges. I think the petals are thin; it appeared glued up and never opened. It has the merit of possessing good foliage, and grows vigorously.

All the rest of my Roses for 1867 I can only speak of as not blooming in their true character, many not blooming at

all, having been severely cut up for budding. Many new Roses do not show themselves in their true character for two or three seasons; others show you what they are, or an approximation thereto, the very first bloom that opens. As an instance of this, I may mention that in 1866, I budded half-a-dozen briars with the new Rose Alfred Colomb. The following season (this year) the buds started vigorously, and in July and August bloomed. Singular to relate, all the blooms that opened on the whole half-dozen stocks were poor and thin. Sentence of death was of course pronounced on poor Alfred Colomb. Soon after this, one fine morning early in September, my attention was attracted to a very fine Rose under a south wall, on a Manetti; it turned out to be Alfred Colomb in all his glory. The colour appeared something in the way of a bright Beauty of Waltham. I was then convinced that Alfred Colomb was a magnificent Rose, with thick petals highly scented, plenty of stuff in it, form and habit of plant superior. We must not be hasty in criticising a new Rose; let them each and all have a fair trial in our gardens. No doubt climate, change of soil, and situation have a great effect on the Rose, and it is certain that hand propagation reduces their stamina. I quite agree with your correspondent, the Rev. N. Pochin, that the French nurserymen puff off their Roses in a manner quite suited to gull John Bull, and with a view no doubt to aggrandize themselves.

Our English nurserymen are not to blame; they generally state in their catalogues of new Roses that the descriptions given are not theirs, but the raisers'. I have been informed that our nurserymen, at the time they buy in a batch of new Roses, know very little about them. All appears to be a complete lottery-bag.

HENRY TAYLOR.

Rose Cottage, Fencote, Bedale.

THE PRINCIPLES OF ORCHID CULTURE.

(A Paper read by Mr. ROBERT WARNER, of Broomfield, at the International Botanical Congress at Paris, August, 1867.)

It will be evident to those who have made the culture of orchids their especial study, that the general principles laid down in the following remarks have in some cases to be modified. It is, moreover, certain that such deviations can only be made by those who have had considerable experience in growing orchids.

It is equally certain that any one following well-defined rules, when commencing any particular study, will be able to experiment with a fairer prospect of success than if he had begun without any settled plan of action.

It is indispensable that the orchid houses should be of a size and shape suitable for the sections proposed to be cultivated. For the northern countries of the continent of Europe, double-glazed houses are almost a necessity. In England they are not so essential, for the cold of its winter is less intense. In Italy they are not required; there the difficulty to contend with is the heat of summer rather than the cold of winter. The width of the houses should not be less than 10 feet or more than 18 feet clear inside; the former should have one path 4 feet wide down the middle, and the latter should have a stage in the centre of 5 feet, with a path on each side 3 feet 6 inches, and side stages each 3 feet wide.

Houses for orchids should be low rather than high. The narrow house should not exceed $7\frac{1}{2}$ feet in height in the centre, and the wide one not more than 10 feet 6 inches. Plenty of ventilation should be provided, both at top and bottom, but chiefly at top, and all openings should be fitted with perforated zinc, to keep out flies and bees, and also to perform the office of respirators. Good but not too thick shading is necessary. The heating power of the boilers and pipes should be 50 per cent. more than is wanted for every-day use. All rain-water falling on the roofs should be collected into tanks within the houses, which tanks should be so placed that the water may soon become of the same temperature, or even 10° warmer than the air of the houses.

For ordinary collections it will be generally sufficient to build two houses, one for the East-Indian and another for Mexican and Brazilian species; for those requiring cooler treatment will do well in any low grapery where only sufficient fire-heat is used to keep out frost, the vines being trained rather thinly, so that only one layer of leaves shall come between the glass and the orchids. The details of cultivation of particular species are best described in Mr. B. S. Williams's "Orchid Manual."

I now come to the time when purchases are to be made, and the first rule I lay down for beginners is, never buy a diseased or weakly plant.

The second rule is, let all orchids, like other plants, enjoy warmth and some moisture during their growing season. It is quite a mistake to suppose that what are termed cool orchids are any exception to this rule, the chief difference being that they require a longer season of rest than others.

This brings me to the third rule, which is one of the most important, viz., let all orchids have a good season of rest. The cooler the climate of their natural habitat, the longer season of rest they require. Some of the East-Indian orchids require but little rest, but even these must have some, if plenty of flowers are wanted. The way of resting orchids varies considerably. With some, coolness of temperature induces rest; in others, the comparative absence of moisture; and, again, there are some that cannot be made to flower unless nearly burnt up by the direct rays of the sun.

The fourth rule is, let plenty of air be given; a circulation of air at all times is desirable, even in winter; whether the air given should be hot or merely warm depends on the section grown, but in all cases draughts of cold air must be avoided.

The fifth rule is, let the utmost care and attention be given to keep the plants free from all insect enemies, whether they attack the leaves by suction or eat the roots, young growths, or flowers. Orchids are not more attacked by insects than the rose and some other beautiful garden flowers.

If the above rules are well followed success is certain, and in many cases the bulbs and leaves will be larger and stronger, and the flowers better and more numerous than in their native countries. It must, however, be borne in mind that orchids will sometimes die, in spite of every care. The members of the human race who can tell the doctors how and where they suffer do not live long, and even an oak-tree, though it may live a thousand years, dies at last.

THE WINTER PRESERVATION OF CULINARY VEGETABLES.

Acting on a knowledge of the hardening effects of autumn transplanting, gardeners have from time immemorial practised it with winter lettuces as well as cauliflower, and (in cold districts) even with cabbage-plants intended for early spring planting, well knowing that, if left in the seed-beds, they have little or no chance of enduring throughout the winter. In very cold upland localities, the transplanting of full-grown broccoli in November is regularly practised, as being the only economical mode of securing a supply of that best of spring culinary brassicæ; and in still more inclement high-country districts, the same mode is adopted for preserving savoy, cabbages, sprouts, the fine yellow but somewhat delicate varieties of german greens, and even "lang kale," which, by being so treated, are preserved almost as certainly as the untransplanted crops of the same kinds are in the least inclement low-country districts. In extremely severe seasons, low-country gardeners, who may have entirely lost their crops from not having adopted the precaution of transplanting at least a portion of them, are scarcely excusable when they offer to their employers, as the reason for the loss, that "the awfully severe frost did it, and they could not possibly have prevented it."

For the benefit of inexperienced amateurs and others, the mode of procedure in transplanting full-grown broccoli and other vegetables in November is here given. Having selected the ground for them, which may either be that in which they have grown, or some other more dry and sheltered place, choose dry weather for the work. Commence by forming a trench of sufficient depth; then take up the plants carefully, allowing as much as possible of the earth to remain attached to their roots, and strip off any decaying or withered leaves. Place them in the trench as nearly upright as possible, at such distances as the extremities of their leaves will stand about 3 inches clear, and so deep that from 1 to 2 inches of the lower portions of the leaf-stems will be under the levelled ground surface. Having thus completed the first row, turn in the earth, and form the next trench at such a distance as to allow of the plants standing about 6 inches clear of those in the first row, that a free circulation of air be allowed around them, and proceed thus till finished. The direction of the rows is not of much importance, but nearly south and north is preferable, more especially when shelter lines of branches are to be formed, as after explained. For late spring broccoli, which grow much between the return of warm weather and the time of their heading, it is advisable to place a layer of good rich manure under the plant, covering it with 2 or 3 inches of soil, so that the roots may not reach it till after killing frosts are past: this will ensure larger heads, and also somewhat prolong the period of their maturing. Similar modes of proceeding are also applicable to other kinds of brassicæ. Late celery is another precarious winter crop which may be treated in a somewhat similar manner. Much trouble as well as expense in rearing it will be saved if it is grown on the surface of richly-mauured ground, instead of in trenches, and only as much earth drawn up about the base of the plants, four or five weeks previously, as to secure them against wind, and give their foliage a compact upright set. In transplanting the full-grown plants, they should, of course, be placed quite upright, and the leaves held closely as well as roundly together, till the earth is placed and compacted about them. Parsley, spinach, leeks, late turnips, parsnips, &c., may also be better preserved throughout the winter by transplantation, modified somewhat from the previously-described modes, according to their different requirements. In the flower-garden, stocks, wallflowers, and other luxuriant-growing soft-wooded plants, may be beneficially treated in a somewhat similar manner, especially when their growth is over-excited by unusually mild autumn weather.

In regard to the best exposures for wintering culinary vegetables, as well as other plants, those lying between south and south-west are to be preferred, unless influenced by local and exceptional causes, as they are less rapidly acted upon by the sun's rays in clear frosty weather than more easterly and northerly exposures, as well as less liable to the sudden returns of evening and night frosts. Walls which face the south reflect most of the sun's heat, and southerly lying wall borders are deemed indispensable for culinary crops; but they are most effective when rows of branch hedges are run across them, so as to protect the crops alike from the early sun's rays and the sweeping winds of winter and spring, against which walls afford but little protection, unless when situated transversely to the wind current. These branch hedges are also of great service when run in a northerly and southerly direction throughout brakes of broccoli, as well as other winter brassicæ, &c., at distances of say 6 to 10 feet apart. A modification of these, in the shape of pea-stakes, are very serviceable when securely set between the double rows of early peas, which can be best done when sowing the latter. In all cases deciduous branches are better for forming those temporary hedges than evergreens, although a sprinkling of spruce branches of from 12 to 18 inches in height may be introduced along their bottom, as anything like overshadowing or drawing up tends greatly to unfit growing plants for resisting cold; hence the propriety of trusting mainly to deciduous instead of to evergreen branches for their shelter, as the former admit of sufficient air and light, while at the same time they secure the plants against the damaging effects of boisterous winds and the injuries arising from early morning sunshine.—*The Farmer.*

DANDELION (LEONTODON TARAXACUM).

To the Arabs, it is said, belong the merit of having discovered its virtues, the name of *Taraxacum* being a corruption, or rather alteration, of their Arabic word signifying edible; but whether they dried and roasted its roots, like the people of Göttingen, and drank a decoction of them instead of coffee; boiled them, as many of the Germans do, like salsafy and scorzonera; or eat the leaves, salad-fashion, like the French, is not recorded. Still, no doubt whatever exists that its medical properties were known to the earliest physicians, so many of them recommend it in all chronic liver complaints; and it has of late years been reintroduced, one may say, into medical practice—not that in cottage domestic treatment it ever went out of repute; for I remember an old woman, known to us as the "herb doctress," who gained considerable fame in the cure of bilious complaints by her wonderful tea, which was nothing more or less than an extract of dandelion, for I often helped her to gather the plant and make it. A pound of the fresh root to a gallon of water, steep the root in the water twenty-four hours, then boil it down to four pints, and strain, will produce a very strong decoction, of which half a teaspoonful twice a day is a sufficient dose for an adult.

The dandelion is so well known that it scarcely needs any description. Its yellow flowers brighten every roadside during the months of April and May, and are very sensible to atmospheric changes, opening wide in fine weather but closing in rain, and at the approach of night.

If you watch the florets of the dandelion when first the sun's rays touch

them in the morning, you will be able to see a motion in them, so sensitive are they to its light; and very few of our common weeds are better provided with the means of propagation than the *Leontodon taraxacum*, or *Taraxacum dens-leonis*, as some modern botanists prefer to call it, for its seeds are wafted by the wind far and wide. The Welsh children call it "daut y lleid," a literal translation of the French *dente de lion*; and I have sometimes known it termed the "hour flower," because they blow away its radiating silky hairs, and reckon the time of day by the number of puffs it takes to clear off the feathery fruit. Many of our small birds live on the seeds of this plant, and pigs are particularly fond of its leaves, and cows do not dislike it.

Water will extract the virtue of the dandelion far better than any spirit, and hence it is that neither extract nor decoction keep well for any period. The root should be taken up in autumn when full grown, and dried for use, but it is far more powerful when fresh. It contains tartaric acid and caoutchou according to Dr. John and Hermbstadt experiments, and is very efficacious in all consumptive diseases.—HELEN E. WATNEY, in the "Farmer."

Calendar.

WORK FOR WEEK COMMENCING NOVEMBER 30.

Kitchen Garden and Frame Grounds.

KITCHEN GARDEN.—Make plantations of rhubarb, seakale, asparagus, and horseradish. Roots of dandelion, packed together in leaf-mould and put into gentle heat, will furnish a delicate salad in five or six weeks. Paskall's seakale pots are best for the purpose. Keep dung and all soluble matters under cover. Turn over manures, and put aside in heaps, to be frozen, rotted leaves, and other materials suitable for potting, and, when well sweetened and pulverized, remove to bins in the potting shed to keep dry for use. Get sticks and stakes tied up in bundles ready for use; wheel turf and weeds to the muck-pit; get pots washed and sorted over, and crocks sifted into sizes for the potting bench. This is a good time to make new drains, improve watercourses, and plant hedges. Sow early peas and beans on warm dry slopes; broccoli to be heeled over with their heads to the north.

POTATOES for planting may now be brought out from the store, and placed in shallow baskets on dry moss or hay, and the baskets put in the full daylight in a position where frost cannot touch them. They will soon green over, and when they begin to sprout the sprouts will be short, hard, plump, purple, and not liable to snap off in the process of planting. We never had such good crops as by this method, and we always plant when the sprouts are a quarter of an inch long; by this time the season will be sufficiently advanced to render the planting a safe operation. The baskets should not be put in a warm place, as there is nothing gained by forcing them into growth, unless they are early sorts to be grown in frames.

CROPS AND RUBBISH.—It is at this time of year we can best judge if the gardener thoroughly understands his business. During summer there is such a luxuriant growth that the most carelessly planted crops oftentimes put on an appearance that wins for their possessor much more praise than he deserves; but nature is no longer in such a friendly and lenient mood, and where the work is badly done the aspects of the place will now reveal it. We expect to see in every kitchen garden at this time of year an abundance of winter greens of kinds suitable to keep up the supply till the spring is considerably advanced, and among these plots there ought not to be found a single withered leaf. The ground not under crops we expect to be clean and in ridges as if freshly dug, and, whatever the nature of the soil, we expect a dry hard path to walk upon, and a breath of wholesome air to keep us cheerful. If we scent the odour of rotting cabbage-stumps and heaps of other such rubbish, we call the gardener a sloven, for he ought to cover all putrefying substances with a few inches of mould to absorb the gases that otherwise escape to poison him and other people. If the place is not clean and tidy, now is the time to make it so by cutting-in overgrown fences, rooting up useless trees and shrubs that intercept the light and exhaust the soil, and clearing the soil of all decaying rubbish, both to economize all such stuff for manure, and avoid loading the atmosphere with gases that render it destructive to human life. Many a village has been half poisoned by a dahlia grower leaving heaps of green stems on the ground for weeks and weeks to rot; many a gardener has to pay a doctor's bill through making his ground into a brewery of stinks; and at least nine-tenths of the diseases in the country arise through the diffusion in the atmosphere of pernicious gases exhaled from stagnant water, foul ditches, and putrefying animal and vegetable substances. "Cleanliness is next to godliness" in the garden quite as much as in the house, and we may be sure that the first of gardeners would not have attained to the age he did unless he had paid more attention to cleanliness than a good many of his successors, who, in the present day, seem to think that dirt is essential to happiness.

Flower Garden.

FLOWER GARDEN.—Bulbs ought to be all planted by this time; but if any remain out of the ground, get them in without delay. Take up Tea Roses that are in exposed situations, and lay them in by the heels in a shed out of reach of frost. Cut down fuchsias that are to remain out all the winter, and cover their roots with litter or coal-ashes. Pansies, pinks, and other choice things in open beds should have a little light litter sprinkled over them in frosty weather, or be protected with canvas on hoops. Tulips protect in the same way. Look over plants in frames, and take off dead leaves, and keep the plants moderately dry.

CARNATIONS AND PICOTEES must have abundant ventilation and very careful watering. Take off the lights daily in fine weather. If any appearance of fly, which is easily detected on the top grass of the plant, fumigate twice. Get in turf from a strong loamy pasture for use next season; lay it up in a ridge till the grass is dead, then chop it over and turn frequently. Every time the heap is turned, put in traps for wireworm, so as to have the mass quite clean by the time it is wanted for use.

HYACINTHS, TULIPS, and other bulbs remaining out of ground may still be planted, and they will bloom very soon after those planted a month or six weeks ago. Plant large bulbs six inches deep, small ones three to four inches deep. If the position is damp, put silver sand under and around all bulbs of any value.

RANUNCULUS AND ANEMONE of common kinds for showy masses may be planted now, but choice and valuable kinds must be kept in the drawers till the beginning of February, and in the meantime get the beds ready by deep trenching and laying up the earth in ridges.

AURICULAS to be kept clean, and to have not a drop more water than will just keep them alive.

BULBS not yet planted must be got in, and as they are unusually fine this season, purchases may yet be made. We always advise early purchasing and early planting; but if we would ever excuse delay it is now, the stock being in such prime condition that the bloom is sure to be satisfactory, though the after-growth may be work through their remaining out of the ground too long.

EVERGREEN SHRUBS planted now must be heavily mulched with dung to keep frost from their roots.

ROSES may be planted now during dry weather; the ground to be in good heart, deeply trenched, and well manured. On loamy land broken up from grass roses do better than in ordinary garden soil, and those who grow for show should either use turf liberally or break up meadow ground for their best plants. Get in briars quickly before the best are gone. Manettis layered during summer may now be divided and planted out in rows for budding next season.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Dig round old fruit trees, and lay down a layer of old dung six inches thick, in a ring, three feet round the stem of each, and the size of the fruit will be improved next season. Trees that are sufficiently luxuriant should not have manure. Root-prune any trees that grow too luxuriantly to bear well. Give protection to any tender fruit-trees, and lay boards in a slope over vine borders to shelter them from excessive cold rains. Unrail from the walls the youngest shoots of tender wall-trees to prevent premature breaking. Let nothing lie in by the heels an hour longer than can be helped. Bush fruits properly taken up and properly planted ought not to miss the move in the slightest degree; but you are sure to lose a whole season if they lie about waiting to be planted. Strawberry beds may be made this month, but it is not a good time to plant strawberries.

BUSH FRUITS should be planted, potted, pruned, and manured. Burn the prunings, and if the ashes are not wanted for any particular purpose, throw them round the roots of trees; they are powerfully fertilizing. Gooseberries and currants may be lightly forked between to mix the manure with the soil, but raspberries should have three or four inches of dung, not very rotten, laid over the piece, and the soil between them should not be dug at all. Orchard-house trees may be pruned at once, and washed with a solution of eight ounces of Gishurst to a gallon of soft water.

Greenhouse and Conservatory.

GREENHOUSE to be kept as dry as possible, and scrupulously clean. If the pavement or tiles are green with conserve, wash down with hot brine and a cane broom, both for the sake of cleanliness and health. The sour, damp odour perceptible in houses at this time of year generally proceeds from the growth of minute vegetation in the form of a green slime, and this is very unwholesome, and probably as much a cause of the ailments gardeners are subject to as the frequent alternations of temperature to which they are liable. Plants in a soft state to be watered with great caution, but none to be allowed to flag for want of water. As water is often retained in little pools about the bottoms of the pots after watering, any containing delicately-constituted plants should be lifted from their places and put elsewhere to drain, to be returned when the battens are dry. On fine bright mornings use a little fire-heat, so as to allow of a free ventilation for a few hours. Chrysanthemums will keep the houses gay till after Christmas, when the first lot of forced shrubs, especially azaleas, will come in to take their place. In the conservatory whatever flowers are at command may be made the most of by judiciously intermixing with them good plants of Yucca, Acacia lophantha, camellias, and others possessing characteristic foliage. Hard-wooded plants in the greenhouse must have as much air as the weather will allow, and as little water as possible, as we may soon expect severe frosts. The thermometer should not descend below 38°. Soft-wooded plants will be subject to mildew if the house is at all damp, and must have fire-heat during foggy as well as during frosty weather. Shift any specimen plants that are in need of increased root-room. Peaches to fruit early must be frequently syringed, and have as little fire-heat as possible, but the heat may be allowed to rise, with plenty of ventilation, during sunshine. Ericas must have air at every opportunity, and, if forced with other flowering shrubs, must have the coolest place in the forcing pit, and be very gently stimulated. Greenhouse temperature 40° to 45°.

AZALEAS AND CAMELLIAS claim attention now that we have little else to depend upon to keep the conservatory gay. A little pains now bestowed in training and disbudding will repay, and Camellias are so heavily set with buds that, generally speaking, it would be most unwise to allow all to remain. We have seen lately bushels of buds removed in some places where a moderate show of fine flowers is preferred to a mass of indifferent ones, the profusion of which will weaken the plants. Azaleas to bloom early to have very moderate bottom-heat, and be syringed daily. Those still at rest to have a rather dry air. Camellias will not stand so much heat as azaleas. As you can get time, clean the foliage of specimen plants.

CLIMBERS in greenhouses may now have special attention to reduce their dimensions. Lay in wood for next summer's bloom, and clear the walls and trellises.

PELARGONIUMS must have a little fire-heat if the house is damp, and the temperature should be kept nearly at an average of 45°. Nice work now when the weather stops outdoor movements to train them into form for blooming, and stir the surface of the soil in the pots, and make the pots as clean as if they had just come from the kiln. The plants will enjoy to be put in Sunday clothes that way. When pots containing plants are washed, put them to drain and dry in a place free from draught, as the rapid evaporation from the outside of the pots causes a chill to the roots.

CALCEOLARIAS for specimens may now want a shift; they must on no account get pot-bound, or they will bloom prematurely. Water on fine mornings, and beware of green-fly and mildew.

CINERARIAS for exhibition to have a shift now into their blooming pots, or they will bloom prematurely through getting pot-bound. Give them the fullest possible amount of light, and keep them a good distance apart, placed on inverted pots, and they will thus have a free circulation of air about them, which will keep them strong and stocky. They will want plenty of air to prevent mildew. Choose bright mornings to water, and get their leaves dry before shutting up. See that specimen plants are in good shape, and peg out the leaves if necessary.

PLANTS IN FRAMES.—Wherever mildew appears cut away the part affected, at once, dust the cut part with sulphur, and admit a current of air, if possible, to hasten the drying of the wound. Remove all dead leaves and decaying litter from among the plants, and if any signs of vermin making ravages, cut

an apple into two or three pieces, and put each piece under a small flower-pot with the hole stopped up, leaving a crevice somewhere under the edge of the pots for slugs and woodlice to creep in. By lifting up the pots every day some will be found trapped, and may be destroyed. A bar or small plank of half-rotten wood laid on the soil at the bottom of a frame will very often attract all the woodlice that are harbouring in it, and on removing it in the daytime they may be discovered and destroyed.

BEDDING PLANTS should be looked over occasionally, and the pits and frames emptied and filled again to clear away all dead leaves and ensure a good airing. Amateurs have many losses through lack of attention to this work, and mildew makes havoc unseen while there appears to be nothing the matter. Short of actual frost, the more air the better; and if water is wanted, give a good soaking on a fine morning when the barometer is high and steady, so that the balls may get a little dry again before a change of weather to wet or frost.

VERMIN.—Now that gardeners have a little breathing time is a good opportunity for cleaning frames, lights, and the under-sides of stages, and other places where vermin harbour. In the stove there is often great need of such work when there is no time to do it.

Stove and Orchid House.

STOVE PLANTS in free growth must have fair supplies of water—not so many times a day, or so many times a week, but as they want it. Plants that have filled their pots with roots, and are now making new growth or pushing for bloom, will need more than those that have plenty of pot-room, and are not thoroughly established. Plants in the warmest end of the stove will enjoy a moderate amount of vapour produced by sprinkling the floor and pipes. One caution must be constantly taken to prevent the entrance of draughts, and especially after watering. Plants at rest to be kept as dry and cool as possible consistent with safety, and moderately well aired. Achimenes and Gloxinias at rest should be packed all together in a dry place. We suppose the cultivator to be able now to furnish the conservatory with showy specimens of Euphorbia Jacquiniflora, Poinsettia pulcherrima, Gesnera zebra, Begonias, Luculias, Camellias, &c., from the stove. But there must be a succession, and one of the first things to consider now is how to make the stove available, not only for the preservation of its ordinary inmates, but to forward furnishing plants for other structures. Plumbago capensis, Cytisuses, Azaleas, and Camellias should therefore be introduced at the coolest end of the stove, if there is room for them; a few Roses may be forced with them, and many ornamental-foliaged subjects will be found useful if in a clean and healthy state. Mixed stove selections must now be kept rather cool, as growth is not desirable. Keep the atmosphere of the house sweet by giving air on fine days, and be careful to remove dead leaves, mosses, and liverworts in pots, and whatever impedes the circulation of air or engenders unwholesome vapours. All plants approaching a state of repose to have little or no water. Plants in active growth must be watered with caution; let them have enough, but see that they do not stand in pans with stagnant water about their roots, or in wet places in the midst of mildew. Temperature of stove 50° by night, 60° by day, with a rise of 10° during sunshine.

ORCHID HOUSE.—In collections where there are now only a few orchids in a growing state, the forcing pit may be turned to account to receive them, so as to allow of the cooling down of the orchid house, and securing thereby a complete state of repose for the plants, which is scarcely possible if there happen to be a few fine specimens pushing into bloom or in an active state of growth. It is at this time of year we see the full value of divisions which can be respectively devoted to orchids from different climates and requiring now different temperatures. Orchids at rest to be kept comparatively cool and dry; 50° by night and 60° by day will be sufficient. Variegated orchids must have very little water now, and if in a warm house, will do better without than with bell-glasses; they are indeed generally kept too close. Rot and spot are diseases peculiar to this season, and are the result of too much moisture in the house or of drip from the glass.

ORCHIDS THAT MAY BE IN BLOOM IN DECEMBER.—Angræcum bilobum, eburneum, eburneum superbum, sesquipedale; Arpophyllum spicatum; Barkeria elegans and Skinneri; Bletia Shepherdi; Brassavola Digbyana; Burlingtonia amœna; Calanthe vestita rubra aculata; Cattleya maxima; Warszewiczia; Cœlogyne Gardneriana, media; Cymbidium giganteum, Mastersii; Cypripedium insigne, insigne Maulei, purpuratum; Dendrobium album, moniliforme; Dendrochilum glumacum; Epidendrum vitellinum; Grammatophyllum speciosum; Lælia acuminata, albida, anceps, Maryanii, peduncularis; Leptotes bicolor; Lycaste Deppeii, Skinneri, Skinneri alba; Miltonia Karwinski; Odontoglossum maculatum, membranaceum; Oncidium Barkerii, bicallosum, Cavendishii, incurvum, unguiculatum; Phajus grandifolius; Schomburgkia crispa; Sophronites cernua, grandiflora, violacea; Zygopetalum brachypetalum, Mackayii.

Forcing Pit.

FORCING.—Keep asparagus going for succession. Rhubarb, seakale, and French beans will soon be in request. Lay a few picked tubers of early potatoes on a warm flue to sprout for planting over dung-heat, and get a bed or two ready.

FORCED PEAS AND BEANS.—Tom Thumb is the best of all peas for forcing; sown now, and grown in pots with French beans, it will give a good return. Those who force for Covent Garden sow in October and November. This pea is of dwarf branching habit, and of very little use for outdoor work, being tender in constitution.

MUSHROOMS to be kept as near 60° as possible, and have plenty of atmospheric moisture. A steady temperature will greatly prolong the bearing of the beds, but if they are nearly at the end of their productiveness, make up fresh beds at once for succession. At this time of year it will be necessary to make a new bed every month to ensure a constant supply.

CUCUMBERS to be started now for the first batch to plant out next month. Sow in pots singly, and grow them on liberally, without running them up two or three together in a pot as if they had been wiredrawn. A dung-bed is the best place for the seed-pots, and the soil in the pots half-rotted turf, well chopped up with half-sweet leaf-mould. Fruiting plants must be thinned if the plants are more than moderately fruitful, or they will fail to give a succession when the fruit may be most desired.

VINES breaking to have a gradual rise of temperature, beginning at an average of 55°, with a rise of 10° during sunshine. As the vines acquire a vigorous growth, raise the heat so as to average 65° by day, and 60° at night when they come into bloom. Too sudden a rise will make long joints and weakly growth, independent of the injury to the crop. A warm dry border will do as much as the best management of the temperature of the house.

Replies to Queries.

Lilium roseum.—B.—The bulb must be preserved from the atmosphere until the spring, and then be potted in lumpy peat, and grown in the greenhouse. We find it best to pot them in the autumn, and give them only as much water all winter as will prevent the soil becoming quite dry, and manage a large collection of liliams on this plan. There is a danger in recommending it, that while the bulbs are dormant they may be destroyed by excess of moisture.

Gladioli.—Rex.—Take up the bulbs at once, and lay them, with all their green leaves attached, in any dry shed safe from frost for a week or two; then clean them and store them in dry earth or sand. In many places they are left out all winter, but we are quite satisfied that the practice could not be recommended for general adoption, because in heavy and damp soils frost would destroy many.

Trees, &c.—Silcotes.—It is useless to wait until they have shed their leaves; take them up at once, and plant them in their new stations quickly. Those who are late in their planting this season will have no excuse, for there has not been known a finer autumn in the experience of the present generation.

Large Currants.—S. S. S.—To obtain large fruit, procure trees of Black Naples, Cherry Red, Raby Castle, and White Dutch; plant them in sandy or calcareous loam, using manure liberally, and every year prune the last growth back to within two inches of the old wood. If a large crop is presented, remove some of the branches. Every autumn put on a coat of manure, and let it be carefully pricked-in between the trees with a fork; the workman to take care he does not touch the roots.

Chinese Paper Plant.—Senex.—It is well known in English gardens; the botanical name is *Aralia papyrifera*. At Kew, Battersea Park, and other public gardens, it is annually planted out, and is one of the most beautiful amongst what are called "sub-tropical plants." We have not known it to flower when so planted out, but it is quite a common thing for the plant to flower in the winter, especially if kept in a warm greenhouse. It would be additionally ornamental if it would flower in the open ground during summer, but that is too much to hope for. As yours is a mild climate and a sheltered spot, it is quite likely the paper-plants would go through the winter without harm, but you must take the risk entirely; we do not advise you to let them remain out.

Aucubas.—W. Harris.—Opinions differ; we consider the true green-leaved female aucuba a handsomer plant than the spotted aucuba of the gardens. The male is hardy of course, but this is not a good time to plant, unless you know the plants selected for planting have been out of doors for some months past. As a rule, they are grown and propagated under glass, and are therefore in too tender a condition for planting out at the commencement of winter. But all who want male aucubas should buy them now to make sure of the pollen, for nursery plants are forward for bloom. Obtain as many males as you want, and put them in a greenhouse or pit. When the flowers expand, collect the pollen with a dry camel's-hair pencil, and keep it in a tin box or any such dry receptacle until the females are in flower. It may be preserved for months if kept dry. Do not force the males at all, rather retard them, but take care that the flowers do not rot in the bud through cold and damp. In April next plant out the males, and thenceforward they will take care of themselves.

Literature.

The City Diary and Almanack (Collingridge, City Press, Aldersgate Street) has again made its appearance. In addition to the matter ordinarily given in a diary for the desk, it contains a large mass of official information with regard to the City not to be found in any other publication, the whole being carefully compiled and well arranged for reference. It is a complete guide to the various business offices of the Corporation and City generally. There is ample space for daily entries, and the blotting-paper with which the diary is interleaved is a very useful feature.

Correspondence.

POYNTER'S EARLY PEA.—Mr. Poynter, in the Magazine of the 23rd inst., having asked for the result of a trial given by me of his early pea, I cannot in justice refuse to give it, indeed, I do so with much pleasure, as it is unquestionably a very early and prolific variety. It was sown on a warm border a week later than "Sutton's Ringleader," and was fit for the table, if anything, a little before the latter variety, and most certainly bore a better crop. I am unable to offer a reliable opinion as to its origin, or whether it be, or be not, the variety named by the Editor, but I hope to give it and a few other of the approved "first early" varieties a fair and careful trial next year, and will not fail to communicate the result to "our" Magazine.

The Laurels, Taunton.

J. B. SAUNDERS.

ORCHIDS CHEAP AND GOOD.

You want to get up a collection of orchids, as you are charmed with the perfectness of the forms of their flowers, their curious development, their wonderful structural arrangement, so ably defined and portrayed by Darwin, and the gorgeous colours impregnated in some species, so wax-like in texture, crystallized as if with drops of silver, and the beautiful combination of colouring, both as regards contrast of colours and shading of some tints, which are not to be seen so blended and contrasted in any other of the great and marvellous floral race. Very well. You must first begin with those coming from great altitudes, enjoying an alpine home in the tropics, and luxuriating in air currents moistened by the dews of heaven. Such are the plants for a novice to begin with, as they are all perfectly at ease in a warm greenhouse temperature, ventilated freely in fine weather, and so managed in winter as to keep a minimum temperature of 40° Fahrenheit. All these plants, which we shall name under, delight in moisture. The artificial climate to which they are transferred must be a moist one, especially at evenings and during night. You may have it comfortably dry

during the day, and promenade with your friends without fear of being parboiled or subjected to the sort of climate which a Turkish bath suggests, for that is the sort of living which most people believe orchids in general to be satisfied with. There never was a greater fallacy, for these plants, as under-named, and many others which we could enumerate did space permit, only stipulate for cool treatment; and if anyone were to treat them, as has been done aforetime, to this sort of life, the sap would be pumped out of the fat-looking pseudo-bulbs, leaving them wrinkled, and their constitutions paralyzed like a used-up apple or potato in May. There are climates of the kind that require to be created to imitate the warm sultry jungles of the East India islands—such, for example, as Borneo, Java, and Manilla, which are particularly rich in *Saccobulbiums*, *Phalenopsis*, *Vandas*, and *Aerides*; but for such beautiful genera as *Odontoglossum*, *Oncidium*, and *Lycaste*, comparatively cool treatment is only requisite.

In going to market, the purchaser who is about to found a collection ought not to select *small plants* of orchids. At best they are but a slow growing race, and, but for continued importations coming to hand, plants of them would be virtually out of the reach of most people inclined to buy. At this day, however, there are "plenty and to spare," and purchasers have ample opportunity of making a good selection of medium-sized plants at reasonable prices. The minimum prices attached to sale catalogues are such as would be remunerative to the seller for the smallest plants he has to offer. The medium-sized-plants may cost a half more, but, being generally better established, they can withstand an amount of fatigue which would kill the smaller specimens outright. It is parsimonious and short-sighted economy, therefore, to deal with the little bits for the mere sake of possession. It requires long experience and an intimate acquaintance with the race to be able to minister to the wants of such as require nursing, and such treatment as will tend to convalescence; ergo the larger-sized plants are really the cheapest in the long-run.

Nothing will repay cultivation better than *Odontoglossum grande*. Clothed with handsome pseudo-bulbs, which are in turn adorned with large dark green leathery-looking leaves, it is an object to please the eye at all times, and when we come to look at it at the period of inflorescence it is gorgeous in the extreme. It abounds in Guatemala, and has been sent home in thousands. Very good blooming plants of it can be had from any house for a guinea—not the price of many soft-wooded novelties—and its value after years' possession, instead of being depreciated, is enhanced. *Lycaste Skinneri* is another Guatemalan subject of first-rate importance, furnishing a succession of bloom for at least six months in the year, and flowering at its best in the dreary months of winter. It is impossible to speak too highly of the decorative character of this plant; for besides being accommodating in the warm greenhouse temperature of this country, it has been proved to be a highly-prized plant for drawing-room decoration: not that the drawing-room atmosphere, and the subdued light which accompanies it, is the place for fairly testing its cultural capabilities, but that physiologically it can be so dealt with during its flowering period without seriously affecting its constitution. The knowledge of this fact is important when we see and estimate the growing desire to have plants of all kinds—the rarer the better—as articles of adornment indoors.

Take another genus, and we have a splendid representative for both effectiveness and cheapness in *Epidendrum vitellinum*. This was found in very elevated regions in Mexico, and has been introduced in quantity in recent years. Coddled as it was wont to be in the hot dry atmospheres of the plant stoves of the country, little wonder that it refused to grow. Now that it is placed in even a cooler climate than the two above-named species, it grows with a wondrous vigour, and flowers so profusely in summer and autumn as to attract general attention. It is a concoloured flower of rather tiny dimensions, possessing a rich, soft, vermilion hue, but it is not uncommon for spikes of it to yield twenty flowers, and when you have size of plant and additional spikes in proportion, the effect is charming in the highest degree.

Peru has furnished a vast host of exceedingly valuable plants for decorative purposes, and many of them are within the province of what we are aiming at in desiderating upon articles both cheap and good. First and foremost among these is *Oncidium incurvum*, a gem of the first water, which has been so knocked about and starved in many of our collections that its best friends have great difficulty in recognizing it. It has fallen a victim to that intertropical stupid treatment which we have so deprecated, and, pining out a miserable existence, its vital energies have succumbed. How different if a promising guinea plant was introduced into the mild, moist atmosphere of a Peruvian climate, such as is exactly suitable for all those we have enumerated! Instead of its pseudo-bulbs becoming wrinkled and its leaves flaccid and sickly-looking, such an eyesore that one would fain toss it, and others in a similar condition, into the rubbish heap but for their value, the bulbs plump up full of sap, and the leaves put on such a lusty appearance as is at all times pleasing. The splendid panicles of bloom which the species yields require only to be seen to be admired, and each individual flower, of lilac and white, is like a miniature doll dressed in gay attire. A large plant of this species, finely flowered, is one of the most beautiful and elegant things that any one could behold. *Oncidium excavatum*, too, is another plant which every one should and could grow. It is a yellow representative of the *Oncids*, a colour predominating in the family. Recently introduced from Peru under the name of *O. aureum*, it will win favour as its merits become known. The species may be considered to be one of the neglected plants, but it is time that it ought to rank differently. It yields immense panicles in the form of corymbs under wise treatment, and is a most telling plant in any mixed collection. Possessed of one of the most robust constitutions, it requires a good diet and plenty of water, and so treated it yields an ample return. As a flowering and an elegant habited plant it far exceeds its cognate species in colour and in growth as the popular *Viola cornuta* does the old *Viola tricolor*.—*The Farmer.*

FIGS IN FLEET STREET.—About a century ago the Rev. William George Barnes, then lecturer of St. Bride's, Fleet Street, planted a fig-tree in the forecourt of a house at the end of Wine Office Court, the history of which is that it was a little slip cut off a famous old tree at a house in Fleet Street, which house had been known by the sign of the Fig-tree. The tree in Wine Office Court attained considerable size and beauty, when, about 1820, the greater part of it had to be cut down, owing to its having been blasted by lightning during a severe storm. But the amputation preserved it, though now only a wreck; and two slips were planted in the area, which have flourished there despite soot and smoke. A great number of fig-trees have been propagated from this stock, and many of them are planted in the country. —*Once a Week.*

The Gardener's Magazine.

SATURDAY, DECEMBER 7, 1867.

THE WINTER DECORATION OF FLOWER-BEDS is so seldom attempted that, from the ordinary aspects of gardens, it might be supposed impossible. Yet, throughout the winter season, all the compartments that have been occupied with flowers during the summer, and especially those so situated as to be within view from the windows of the dwelling-house, might be richly furnished at a very trifling expense. In our essays on the "Plunging System," we have endeavoured to show that the compartments adjoining the residence, and especially the most highly-dressed portions of a terrace garden, might be kept gay at all seasons by the employment of plants in pots, systematically grown in quantities for the purpose. To furnish any considerable extent of ground, however, by the plunging system would be so costly that it is not to be thought of for the parterre *in extenso*; and, indeed, it is only for very select spots—choice entrance courts, and beds and borders nearest the windows,—that we have advocated its adoption. For all the larger spaces, the simple and comparatively inexpensive plan of planting evergreen shrubs is worthy of adoption. While these things are small, they may be planted in tasteful groups in November, or later, and be wholly removed and replanted in the months of March and April following, without being in the least injured by the proceeding. Thus they may be made to do duty in the parterre throughout the winter, and contribute to the beauty of some other portion of the grounds during the summer, or may go to the reserve garden, and be forgotten till wanted again.

It scarcely need be said that a little taste and judgment must be exercised in carrying into effect a suggestion of this kind. In the first instance, if the trees are to be planted in the beds without being prepared for the purpose by pot-culture, the smaller they are the more likely are they to bear such treatment without injury. But if potted trees are plunged, they may of course be grown on to any size consistent with the wandering life they are to follow; and so long as they can be lifted they may have larger and larger pots, and grow as freely as they please. But for temporary planting trees one to three feet high should be preferred to those of larger size. The planting in the beds should be done with as much care as if they were intended to remain there; and it would be well to plant them rather deep, both to secure the roots against the possibility of injury by frost and to give them a firm hold, and prevent the stems being loosened by the wind. The transplanting from these beds to the quarters they are to occupy the next summer must be still more carefully performed. In the first place, the trenches and stations they are to be transferred to should be well dug and broken up, and unless the soil is already of a rich, friable, kindly nature, a liberal allowance of good rotten manure should be afforded for all except coniferous trees, and these should have the aid of leaf-mould. If they are transplanted immediately after the easterly winds that usually blow in March have spent their animosity on the land, they will probably make roots immediately in their new quarters, and require no more care. But if east winds blow for any length of time after their removal, they are likely to be somewhat browned and impoverished. Nevertheless the risk of injury is extremely small, provided proper care is taken in the management.

No. 136, NEW SERIES.—VOL. X.

In the selection of trees, those kinds which may be purchased at a low price in quantities are to be preferred. Two of the most distinct and generally useful kinds are the common Aucuba and Berberis aquifolium. The common Euonymus is peculiarly rich and cheerful in the winter season. There are several varieties of Box, both green and variegated, that may be employed, and we must not forget the exhaustless variety of the Holly. Mere curiosities are of little use; we want distinct, bold, massive plants. The Irish Yew, while small, is an admirable subject to intermix with round-headed bushes of cheerful colour. Amongst coniferous trees, the common Junipers and Firs are to be preferred for the Planting System, but in this great department of the vegetable kingdom there is ample room for choice.

The Plunging System, where it can be carried out in its integrity, renders the region to which it is applied as beautiful, if not so bright, in winter as in summer. By systematic cultivation of suitable plants in pots, a grand system of grouping may be carried out with subjects that are noble and various in aspect, and rich in points of interest for the observant cultivator. From the genus *Hedera* alone we may derive materials for the complete furnishing of a winter garden. The fine chocolate hue of the Poet's Ivy, the light green, orange, and reddish hues of the Algerian Ivy, the rich dark green of the common Irish Ivy, the solemn blackish tone of Regner's Ivy, and the bright creamy, rosy, and silvery hues of the variegated-leaved ivies, afford such abundant variety, combined with a delightful freshness of colouring, that we may safely pronounce the cultivation of these plants in pots to be one of the first necessary steps towards rendering our gardens as beautiful during winter as they might be with the wealth of material at our command. But we may add to these many other beautiful subjects, which can only be made available for the winter garden by systematic pot-culture—such, for example, as the Skimmias, with their abundance of red berries; the *Cratægus pyracantha*, with its huge branches of fiery scarlet berries, the yellow-berried tree Ivy, a host of handsome Japanese shrubs; and it begins to be time to look for berry-bearing Aucubas in the winter garden, and there can be no better way of displaying them out of doors than to fertilize pot-plants, and plunge them out in groups when the flower-beds are emptied.

Very much has been said in praise of the variegated Kails for winter decoration. They have had a long and a fair trial in the experimental plunging garden at Stoke Newington, and after all we cannot say much in praise of them. Their colours are rich and various, the cut-leaved varieties are extremely elegant, yet when grouped amongst plants of such high finish as our specimen ivies, the cabbage is betrayed, and what promised to look like Hyperion is little better than a Satyr. For the shrubbery borders these kails are well adapted, and in the kitchen garden their appearance is truly splendid; but when transferred to a place where artistic finish is studied, they look coarse, inappropriate, very ungainly make-shifts. There is this grand objection to their use in any garden or part of a garden where a trim, neat, and lively tone is required, that in bright frosty weather, when evergreen shrubs sparkle and shine, these Kails drop their leaves and look like heaps of coloured rags.

THE SPANISH ONION OF THE SHOPS is frequently the subject of inquiry amongst cultivators, and the notions that prevail respecting it are of a most hazy nature. It is quite certain that no English-grown onions ever equal these in size, beauty, and mildness of flavour; yet there are many who would do their best to grow such, could they obtain a true sample of the veritable seed from which these handsome bulbs are raised. If inquiry were made at random of experienced cultivators, a great variety of answers would be given respecting the proper name and identification of this variety. A great many onion growers would assert it to be the Brown Portugal, differing from English-grown roots of the same only to such an extent as might be accounted for by being grown in another climate. A great many would vote for Brown Globe, some for Globe Tripoli, and a few, perhaps, for the handsome and rather tender-habited Giant Madeira. But the plain truth about this onion is, that it has no name in English gardens, and would not be of the least use to us were it introduced, and the genuine seed

freely offered from the seed stores. The proper name of this variety for purposes of identification, or for place in any list, is the PORTUGAL ONION; and this name is justified by the fact that Lisbon is the centre of the export trade through which our shops are supplied. This variety is extremely tender in constitution and therefore but ill adapted for cultivation in this country, which is sufficient to account for its absence from our seed-lists. It is variable in form, but always inclining to globular, and has a peculiar bright brown outer skin. Its mild sweet flavour is characteristic of it as a variety, for when grown in England, as it has been, frequently from imported seed, it is milder than most other English-grown onions, but in this climate it never attains to the size, the finish, and the delicate flavour for which the imported bulbs are so justly prized. This variety is readily distinguished from other kinds when growing by its bold bright green leaves, which are more robust than those of any other variety, and when drawn in a young state it is found to root deeper and more diffusely than any other kind. It does not keep long, and, all things considered, is not worth growing in English gardens, for though distinct and peculiar, it is much more the product of intense sunshine than of the course of breeding by which, in the first instance, it was obtained.

DEATH OF MR. MCNEILL.—It is our painful duty to announce the death of Mr. McNeill, of the Chief Secretary's Gardens, Phoenix Park, Dublin, which took place on Tuesday, the 26th of November last. Mr. McNeill will long be missed from the large circle of friends, by whom he was esteemed alike for his fine social qualities, his extensive and varied knowledge, and his genuine goodness of heart. As a plant-grower he had few equals, and his botanical acquirements were far in advance of the average of men occupying similar stations in life. He has left a widow and a young family to lament his loss, and miss him more than the best of his friends can do.

EXCURSION TO THE HOLY LAND.—An excursion has been planned by Mr. Gaze, of Southampton, for the early part of next year. It is proposed to form a party for the purpose of visiting Egypt and the Holy Land, going through Paris and Italy, and returning *via* Constantinople, Hungary, and Austria, the entire journey occupying rather more than two months, during which time the company are to be entertained in first-class style, put up at the best hotels, travel in the most approved fashion, and, where necessary, have military escort. The expense, considering what is to be done, is not great—£150 being the cost to each member of the party. Mr. Gaze has furnished such ample proofs of his ability to carry out a matter of this kind, that his name will be a guarantee for the general excellence of the arrangements.

AN ENORMOUS CHEESE, weighing $3\frac{1}{2}$ tons, in which the amount of milk used was equal to one night's milking of 15,000 cows, has been brought here from the United States for exhibition. It is, we believe, at present at Liverpool.

THE FIRST SNOW in 1867 fell on the night of Sunday last, accompanying a great gale which strewed the coasts with wrecks, and was so violent in the metropolis as to occasion a number of disasters. The splendid autumnal weather, which was the cause of universal rejoicing, came to an end on Saturday, the 30th, when the barometer fell, and heavy rain poured down. On Sunday the barometer continued to fall fast, and the rain became a deluge, while the wind rose almost to a hurricane. During the night of Sunday the barometer rushed up, and a stiff breeze blew; the ground was frozen hard on Monday morning, and on their windward sides the trees were coated with ice. According to the almanac winter commences on the 22nd of December at 6h. 46m. a.m.; but according to our sensations, and the aspects of nature, winter began on Sunday last. The following record of observations made during the few days of "extraordinary weather" at Stoke Newington may interest some of our readers:—

Friday, Nov. 29, 9 a.m.,	bar. 30.23;	Negretti's Aneroid, 30.22;	therm. 29°

CALCEOLARIA PISACOMENSIS, a Peruvian species, introduced by Messrs. Veitch and Son, and first flowered in England by them in the nursery at Chelsea, is the subject of an attractive figure in the December number of the *Botanical Magazine*. The flowers are of large size, and in general aspect resemble the flowers of a papilionaceous plant; the colours are bright red and orange. We call attention to this splendid plant as admirably adapted for the operations of the hybridizer, and as likely to furnish new and useful material for garden embellishment. It is a strange thing that although there are dozens of splendid species of calceolaria known, a mere fraction of the number are in cultivation. They are successively introduced, flowered, figured, and forgotten. We hope the one now before us will find a permanent place here.

THE BORER has been the subject of several serious complaints from cultivators in America and India during the past few months. The following is one amongst the many extracts from the papers in which accounts of its ravages have been made public; it is dated from Madras, Sept. 24th: "How many of your readers, I wonder, have heard of the 'Borer'? I never myself remember to have seen its name in any English newspaper. But here, in Madras, it has long filled the columns of our press, and lorded it over our dinner tables, until just now it had to give place to the Abyssinian Expedition. It is a kind of small grub which infests coffee plantations, and which in the coffee districts of this Presidency has done, and is doing, mischief incalculable. A planter told me yesterday that on one of his estates, 320 acres, or about 400,000 trees, had in one season been entirely and irrevocably destroyed by it. He estimated the yearly produce of these trees at £10,000, and considered that of this about one-half was net profit. The destruction was so sudden as to be inevitable. He had no intimation whatever of danger until he saw the leaves turn yellow and droop, and the

trees were then past all hope. This may have been an exceptionally bad case (I mean as regards the extent of the calamity, not as regards the nature, which is almost invariably the same), but there are many more very like it. Here and there planters have been positively ruined, and obliged to give up their estates and leave their homes. There is a report that the Madras Government think of appointing a special commissioner to investigate the subject, and it is, without doubt, well worthy of Governmental notice, for though many doughty champions have entered the lists against him, and many schemes have been confidently recommended for his overthrow, the Borer does not yet seem to have found his match." Turning to the *Scientific American*, we find that our transatlantic cousins have found a means of matching this destructive caterpillar, though the process appears to be costly. The borer works in secret and is not likely to be found, therefore to devise means for its destruction appears at present futile. But it is possible to pre-

vent its attacks by the adoption of the apparatus here figured. This is especially intended for peach-trees, although adapted to other fruit-trees. It is a cylinder of sheet metal pierced with minute holes for the admission of air. It can be opened and placed around the trunk of a tree, and secured by a rod passing through ears which project through holes in the outside lap of the cylinder. The cylinder is sunk a few inches in the earth and held by the soil being pressed around it and over the feet or legs secured to it. At the top is attached a piece of oiled cloth or painted canvas the top of which is held closely around the trunk by a string. The longitudinal seam is then sewed up or secured by a cord run in, so that all is kept tight below that point. A patent for this device was obtained Jan. 16, 1867, by George W. Dudderar, of Unionville, Md., whom address at that place for any additional information desired.

HIBBERD TESTIMONIAL.

When the testimonial was proposed, I made a few brief remarks, to indicate that I was aware of the intentions of my friends, and should leave them to work out the scheme in whatever way appeared to them best. It must, I hope, be evident to all that I did not trim my sails to catch the breezes of public favour in any sort of way, and perhaps it may be known that immediately after the proposal was made circumstances occurred which compelled me, in defence of my own integrity and independence, to convert into enemies many who in this testimonial business had promised to be valuable friends. Well, right or wrong, I have followed the course which I am sure honest men will approve. I have not allowed my interest to influence my judgment on any question with which it was my duty to deal. It is gratifying now to know that though I must have wounded deeply, however unavoidably, a considerable portion of my immediate connexion, the testimonial closed with a well-filled purse, which was gracefully handed to me by the committee, accompanied with expressions of feeling which increase my obligations far beyond the actual value of the gift. But those obligations are pleasurable; they give additional warmth to my thanks, and help me, by the assurances they afford of the appreciation of labours that have been rendered with a larger desire to do good than to secure personal benefits. I might believe I was not labouring in vain, but the testimonial is an assurance of such a wholesome faith, and I am bound by it to increased diligence, watchfulness, and earnestness in the discharge of every duty. To the worthy treasurer, Mr. James Crute, and to Mr. James Coldwells, the honorary secretary, I offer my heartiest thanks and assurances of esteem; I value the time and strength the Committee have bestowed in my service, and I accept with gratitude the many tributes of personal regard which have accompanied the subscriptions. To ALL who have aided, whether much or little, I am bound by every good feeling which should attend the reception of a gracious gift, and I beg them to receive the grateful acknowledgments of their devoted servant,

SHIRLEY HIBBERD.

Stoke Newington, London, N., Dec. 3, 1867

MIGHT AND MANE.—Lord Charles Somerset was telling a long story about his walking in the woods at the Cape one day, when he came suddenly upon a huge shaggy lion. "Thinking to frighten him," said the noble lord, "I ran at him with all my might." "Whereupon," said another, interrupting, "he ran away with all his mane." "Just so," said the lordship

Exhibitions of Chrysanthemums.

BRISTOL AND WEST OF ENGLAND.

We have spoken of the Brixton and Stratford exhibitions as the best in connexion with the metropolis, and now it is our duty to say that the Bristol exhibition surpasses in plan and detail all others in the empire. The present exhibition was indeed an advance upon all former displays of the kind, and, we scarcely need add, that completeness, richness, and variety were secured by adding to the chrysanthemums fine-foliaged plants and fruits. The Drill Hall, Queen's Road, where the exhibition was held, is admirably adapted for the purpose; it is spacious, not devoid of elegance, and well lighted; the comfort of visitors is therefore secured, which is a matter of as great importance as the quality of the exhibition. The chrysanthemums were ranged round the hall in a series of bold groups, and on a long table in the centre the stove and greenhouse plants, the cut flowers, and the fruits were placed.

PLANTS.—In the class for 9 *large*, Mr. J. P. Budgett took first place, with plants of enormous size, in perfect training, and with foliage and flowers fresh and abundant. We are inclined to think that this group would have taken first place had all the first-prize lots of the season been shown against it; at all events, they surpassed by far the average best we are accustomed to in London. The varieties were Golden Queen, Prince Alfred, Queen of England, Arigena, Lord of the Isles, Jardin des Plantes, Christine, Alma, and another. Mr. Barnes second, with Golden Queen, Sparkler, Queen, Her Majesty, Mr. Jay, Cherub, Lady St. Clair, Empress of India (same as White Queen), General Bainbrige. In the class for 6, Mr. Budgett first, Mr. Barnes second. In the class for 3, Mr. Budgett and Mr. J. H. Nash were the prize-takers. 9 *pompons*: 1st, Mr. Budgett, with Mr. Astie, Andromeda, Golden Circle, Bob, Bijou d'Horticulture, Aigle d'Or, Hélène, Miss Nightingale, and another; 2nd, Mr. Nash with Bijou d'Horticulture, General Canrobert, Salomon, Alexandre Pelé, Golden Aurora, Madame E. Domage, Aurora Borealis, Golden Circle, Hélène. 6 *pompons*: 1st, Mr. J. H. Nash; 2nd, Mr. John Jones. 3 *pompons*: 1st, Mr. Budgett; 2nd, Mr. C. Fisher. A splendid specimen Golden Queen of England was shown by Mr. Budgett, and Mr. Barnes presented a fine specimen Golden Christine.

In the classes for amateurs not keeping gardeners, there were some well-grown plants shown. 3 *large*: 1st, Mr. T. Rugg, with Prince of Wales, Golden Christine, and White Queen of England; 2nd, Mr. Yeates. 3 *pompons*: 1st, Mr. Yeates, with Madame E. Domage, Cedo Nulli, and Golden Cedo; 2nd, Mr. Rugg. In other classes the principal exhibitors were Messrs. Budgett, Barnes, Nash, Jones, and Rugg.

CUT FLOWERS.—24 *large incurved*: 1st, Messrs. Garaway; 2nd, Mr. T. Hobbs. 18 *ditto*: 1st, Mr. W. H. Morgan, of Plymouth, with as fine a lot of flowers as we ever remember to have seen on an exhibition table. We trust the exhibitors who came from distant parts—and there were a few even from London—took notice of the shape and make of these flowers, which had received but a small amount of dressing. 2nd, Messrs. Garaway. 12: 1st, Mr. Morgan; 2nd, Mr. Hobbs. In other classes the principal exhibitors were Messrs. W. H. Morgan, E. Rowe, of Southampton, and T. Hobbs. There were two classes for vases of flowers, one open and the other for ladies only. In the open class Mr. T. Canning took first place; 2nd, Mrs. M. Parsons. In the ladies' class, 1st, Miss Dodds; 2nd, Mrs. M. Parsons. Amongst the novelties was a superb bloom of *Bronze Jardin des Plantes*, from Messrs. Garaway and Co., of Bristol. This is a bronze-coloured sport from the celebrated *Jardin des Plantes*, and has all the fine qualities of the parent.

MISCELLANEOUS.—Although the miscellaneous subjects were subsidiary to the Chrysanthemums, they played a very important part in the filling up of the splendid scene. In the centre of the hall was a grand group of plants from Mr. J. Nelson, of St. Michael's Hill Nursery, for which a first prize in the class for a collection was awarded. A conspicuous member of this group was a plant of *Latania Bourbonica*, spreading 10 feet over; and also noticeable for magnitude and beauty were specimens of *Cycas revoluta* and *Dracena forrea variegata*. Mr. Budgett took second place in this class. A beautiful group of six fine-foliaged plants was contributed by Mrs. Miles; they were fresh and bright, and all good varieties. Mignonette plants from Messrs. Budgett and Barnes, superb; their delicious fragrance pervaded the whole of the room. Collection of plants in flower: 1st, Mr. T. Canning, with *Statice profusa*, *Hoya carnosia*, *Allamanda Hendersonii*, *Ixora Javanica* and *coccinea*, and another; 2nd, Lady Mackworth and Mr. J. D. Weston (equal). Nothing amongst the miscellanies proved more attractive than the *Poinsettias*, of which there were numerous beautiful specimens, bearing richly-coloured bracts. Mr. W. H. Wills took first prize in the class for six with glorious examples, and Mr. Budgett took second prize with plants admirably grown. Amongst the curiosities of a miscellaneous kind, special mention must be made of the female *Garrya elliptica*, in fruit, from Mr. C. W. Finzel, who also sent some ripe fruit of *Philodendron pertusum*. There were also examples of *Aucubas* bearing berries, some superb egg-plants and capsicums, several vases of flowers and fruits arranged for table decoration. The fruit classes were well filled, grapes, pines, pears, and apples constituting the principal features. The prize-takers in these classes were Earl Ducie, Lady Mackworth, Mr. H. G. Ludlow, of Westbury, Mr. Sampson, Mr. R. Thornton, Mr. W. Elger, Mrs. Miles, Mr. H. W. Green, Mr. R. P. King, Mr. Richards, Mr. Holder, and Mr. T. Taylor.

ROYAL VICTOR, OLD FORD.

This was a pretty exhibition on a small scale, which proved highly attractive to the inhabitants of the district.

PLANTS, 3 *large*: 1st, Mr. Baynter, with Gloria Mundi, Annie Salter, Princess Louis of Hesse; 2nd, Mr. Ball, who had a good Lady Harding, with others. 3 *pompons*: 1st, name not given, the plants were Mrs. Wyness, White and Golden Cedo; 2nd, Mr. Ward, with Salomon, Golden Cedo, and Astrea; 3rd, Mr. Fisher, with Canrobert, White Cedo, and another. 3 *standard pompons*: 1st, name not given, the plants were neatly-trained examples of Antonius, Aurore Boréale, Golden Cedo; 2nd, Mr. J. Ball, with White and Lilac Cedo, and another. 3 *pompons without training*: 1st, Mr. Eickhoff, with White Cedo, Mr. Astie, and Canrobert; 2nd, Mr. Pilgrim, who had good plants of Antonius and Golden Cedo; 3rd, Mr. Cormick, who had a fine Lilac Cedo. Other contributors were Messrs. Fisher, Baynter, J. Ward, and J. Ball. Mr. Baynter won the Royal Victor Cup with 6 splendid pompons.

CUT FLOWERS: 12 *large dressed*: 1st, Messrs. Henderson, with Empress of India, John Salter, Venus, Rev. J. Dix, Jardin des Plantes, Prince of Wales,

White Globe, Prince Alfred, and others; 2nd, Mr. Long, with Beverley, Cherub, Novelty, Oliver Cromwell, Prince Alfred, and others; 3rd, Mr. Cousens. 12 *large, as grown*: 1st, Mr. Peachey, with White Globe, Prince Alfred, Dr. Brock, Golden Dr. Brock, Beverley, Venus, and others; 2nd, Messrs. Henderson, with Prince Alfred, Beverley, Lady Harding, and others; 3rd, Mr. Long; 4th, Mr. Flowers. 6 *large dressed*: 1st, Mr. Wheldal, with Beauty, Golden Beverley, Pio Nono, Prince of Wales, Her Majesty, Mrs. G. Rundle; 2nd, Messrs. E. G. Henderson and Son, who had fine examples of Prince Alfred and Prince of Wales; 3rd, Mr. France. Other contributors were Messrs. Long, Eickhoff, Cousens, Baynter, Burnham, and Fisher. 6 *large, as grown*: 1st, Mr. Wheldale, with Cherub, Beauty, Mrs. G. Rundle, and others; 2nd, Mr. Peachy, who had fine blooms of White Globe and Beverley; 3rd, Messrs. E. G. Henderson, who showed Prince Alfred, fino; 4th, Mr. Burnham, who presented a splendid White Queen. Other contributors were, Messrs. Baynter, R. Fisher, Jones, and Smith. 12 *anemone-pompons*: 1st, Mr. Eickhoff, with Madame Montels, Mr. Astie, Miss Nightingale, and others; 2nd, Mr. Flowers, with Sidonie, Marie Stuart, and others; 3rd, Mr. Cousens. Other contributors were Messrs. Warren, Pilgrim, and Ball. 12 *trusses of pompons*: 1st, Mr. N. Hemmings, with a bright assemblage; 2nd, Mr. Ward. Mr. France presented an extra lot of large flowers of fino character, for which he was awarded a first place. Mr. Long, second in the extra class. Master J. Ball embellished the table with a pretty aquarium.

The prizes were distributed at a meeting held at the Royal Victor, Nov. 23rd, when Mr. Nichols presided. In several instances these were in money or plate, but in some of the classes implements and books were given, such as watering-pots, gardeners'-knives, thermometers, and Salter's Treatise on the Cultivation of the Chrysanthemum.

LIVERPOOL.

The November exhibition of the Liverpool Horticultural Society was better this year than ever, for fruits were shown in abundance, and the high-coloured varieties of apples were more brilliant than usual, and the chrysanthemums were throughout of better quality than heretofore. There is yet room for improvement in the treatment of chrysanthemums in this part of the world; but we see the Liverpool cultivators are progressing satisfactorily, and have no doubt they will equal their brethren of London and Bristol soon, for the great eastern and western cities at present divide the highest skill between them. The best groups of large-flowering chrysanthemums came from Mr. Hignett, gardener to C. Row, Esq., who is evidently a master of all the forms and all the varieties. His huge round bushes of the large-flowering kinds, his dwarf and standard pompons, were superbly done, and won for him the honours he deserved. In the nurserymen's classes, Messrs. Matthews, Whitfield, and Wilson were the principal exhibitors. The varieties shown included nothing new or special, being such as have had prominent notice in other reports. The cut flowers were decidedly poor, the cultivators having apparently been timid in respect of thinning, but the chief defect was in the dressing, some very fair blooms lacking just a few touches to give them their proper character.

Miscellaneous flowers were agreeably various, and, amongst ferns, primulas, mignonette, and poinsettias, it was delightful to see the pure white spikes of the little Roman hyacinth, one of the best bouquet plants known.

Fruits were admirably shown, and, as a matter of course, Mr. Meredith, of Garston, presented some splendid grapes. The principal collection from this cultivator was not intended for competition. It comprised Black Alicante, Gromier du Cantal (the Alicante of the vineyards of the Garonne), Child of Hale, a small-berried white grape which makes huge bunches; White Tokay, Foster's Seedling, Lady Downe's, and a bunch of Barbarossa that was ripe in May last and was now in perfect condition. These were all in the true Meredith style; we need not say more in their praise. The finest muscats in the competition classes came from Mr. Hill, of Keele Hall; these were grand in berry and colour. Fine samples were also shown by Mr. Blissett, gardener to H. Phillips, Esq. and Mr. Reid, gardener to S. P. Hope, Esq. The finest Black Hamburgs in the classes came from Mr. Woolley, gardener to W. Jackson, Esq., Birkenhead. The best Barbarossa from Mr. Sorley; these bunches were far above average size, and the berries were of the largest, and in perfect colour. Mr. Rawbone presented fine Alicante and Trebbiano. Pines were not plentiful; Mr. Freeman, gardener to the Earl of Derby, presented beautiful examples of Black Prince and smooth-leaved Cayenne.

Collections of fruits were admirably shown by Messrs. Woolley, Forbes, and Smith, and by Messrs. Rylance and Ashcroft, nurserymen. In these collections the most noticeable grapes were West's St.-Peter's, Black Hamburg, Muscat of Alexandria, Barbarossa. Pears: Marie Louise, Beurré Diel, Beurré Bosc, Ducaon's Incomparable, Beurré de Rance, Glou Morceau, Winter Nelis, Duchesse d'Angoulême, and Easter Beurré. Apples: Cox's Orange Pippin, Cox's Pomona, King of the Pippins, Ribston, Blenheim Orange, Court-pendu-Plat, Beachamwell. A dish of Raby Castle red currant was thought worth noticing, as the fruit was fresh and good, as if but lately ripened. In the classes there was a good competition, Messrs. Sorley, Reid, Whitfield, Smith, and Lowndes divided honours in the classes for pears; Messrs. Smith, Reid, Woollam, Freeman, Turner, and Thomson, in the classes for apples. The best culinary apples shown were Emperor Alexander, Blenheim, White Calville, Reinette du Canada, Flower of Kent, Golden Noble, Catshead, Kentish Fill-basket, Mère de Ménage, and Hawthorn.

THE CENTRAL HORTICULTURAL SOCIETY.

On the evening of Tuesday, the 19th ult., the members of this useful institution met at Dr. Johnson's Rooms, Essex Street, Strand; Mr. George Gordon, A. L. S., the president, in the chair. The lecture table was graced with an abundant supply of the finest flowers and fruits of the season, and consequently presented a refreshing and somewhat tempting appearance. The chrysanthemums were especially fine; many of them had been grown in the gardens of Buckingham Palace, and were kindly lent by Mr. Wyness, a member of the society. Several cases of grapes, the product of the ground-vineries of Mr. Wells, at Southend, are also entitled to high commendation both as regards fineness and flavour. The principal business of the evening, however, consisted in the reading of a paper by Mr. Joseph Newton, the well-known landscape gardener, on "The Approximate Principles of Chemistry as regards Horticulture and Agriculture." The essayist remarked upon the necessity of combining an accurate scientific knowledge of the varied elements of which soils are composed with lessons gained by experience and observation. He entered largely into detail as to the practical treatment

necessary for causing the earth to yield its maximum of sustenance to the numerous plants and animals which subsist upon its surface and productions, and showed that by judicious management the most sterile soils might be made fruitful. Especial attention was directed to some portions of the fens of Lincolnshire, as illustrations of his views. Mr. Newton demonstrated that it was possible also to convert unhealthy localities, reeking with miasma, into sites desirable for human habitation, and quite free from the exceptional diseases which had previously infested them. In short, the paper read was throughout instructive and valuable, not only to those engaged in agricultural and horticultural pursuits, but to the student of nature and the philanthropist.

An animated discussion followed, and in this Messrs. Green, Warren, Wells, Mr. Gordon, the president, and others, participated. Finally, in proposing a vote of thanks, Mr. J. Newton, of the Royal Mint, regretted that the proceedings of the evening had not been shared in by a far larger audience. So admirable an institution, he considered, should be liberally supported.

THE PEAR, WITH SOME REMARKS ON ITS CULTIVATION AND MANAGEMENT.—No. II.

Having dealt with the management of the pyramid form in my last article, I have now to refer to the fan-shape for walls, and the remarks I made in my last with reference to the kind of stocks and soil will be applicable to this form of tree. The point of greatest consideration should be the positions we can give them on the wall; very many, and I may say too many, fill all the best parts of their walls with such subjects as peaches, nectarines, &c. This is all very proper, no doubt, for those who may like a glut of summer fruit, and none for the autumn and winter. But I happen to know that, although many like a good display of fruit in summer, they also like a few good pears in the winter, and, in fact, very often feel disappointed at their absence from the table. I also happen to know that they would be willing to see a less number of peaches, &c., eaten up by wasps and other insects, and so spoilt, if they could but have the gratification of seeing good dishes of pears during the winter. But as the filling of the walls is generally left to the discretion of the gardener, the proprietor no doubt often feels that he has not much room for complaint, as he is abundantly supplied during summer, and he can see that the walls are well covered with trees. But this is the difficulty that disappoints the owner, and is certainly not very creditable to the gardener's ideas of management. The walls are thickly studded with trees, but the majority of them are only such as produce fruit of a very perishable nature. Variety appears to have no charms for some gardeners, while it is, above all others, the one thing needful in every good garden. The gardener delights in growing peaches and nectarines, because it is generally considered that they require more skill in cultivating them, and as to whether all he can grow on his south and south-west walls will be consumed by the family, he never has a thought. These positions are too good for such common things as pears, he says, and so he goes in for peaches, gives his employer a thorough feast while they last, and consoles himself with the thought that his master ought to be satisfied with the abundance of the moment, and even feels hurt if there should be even a hint given about the absence of fruit on the dessert table during winter.

But this is not as it should be. The proprietor of a garden who pays liberally for its management, is entitled to something more than a few weeks' supply of fruit, and, in opposition to the prejudices of the gardener, he may reasonably demand it, and no man ought to make a stumbling-block of such wishes. But pears generally are so little known and appreciated by some gardeners, that they look upon them as intruders when they see a more sensible cultivator growing some favourite sorts upon a south or south-west wall. I heartily wish it was in my power to collect the whole posse of such gardeners into a circle next February, so that I could present to each a nice ripe fruit of the *Ne Plus Meuris*, and compel them to eat it; and all those who did not acknowledge its claims to notice as a desirable fruit to cultivate on a south wall I would have banished till their views were changed. The fact of the matter is, amongst some gardeners the pear is not a popular subject; it is looked upon as a common tree by those who know anything about it, and they are not many; and some would discard it altogether to make room for subjects that are higher in favour. But the owners of gardens must see to it, for I must give up in despair the hope of ever converting the gardeners to a belief of the high state of perfection the pear may be brought to in this country. It is only reserved for a few earnest cultivators to know this, and they, knowing their value, ensure for them the conditions favourable for the development of their perfections, and until this is more generally done a wider knowledge cannot be obtained. Surely it is better management of a garden when its occupants embrace all that is good and various, instead of being confined to a few subjects that give a supply only for a limited time, and that of subjects closely allied!

The superior excellence of such varieties as the *Ne Plus Meuris*, *Easter Beurré*, *Beurré Rancee*, *Josephine de Malines*, and many others, ought to win for them a position more favourable than a cold north or east wall; while such varieties as *Beurré Diel*, *Beurré Bose*, and the *Chaumontel*, should be comfortably ensconced on a west or south-west wall. Indeed, if the cultivator wishes to have them in perfection, he must so place them, or else he must be content with the miserable samples we too often see.

I must now hasten to more practical details. Assuming that the positions for the trees are well drained, and the soil deeply trenched up, I would advise the cultivator to secure early in October, or as soon after as possible, some trained trees of sound make and shape. They should have been trained two years before at least—three years would be better—as the larger the trees, the earlier will they come into bearing; and large trees will remove with as much certainty as smaller ones, if they have been properly handled.

The annexed sketch is a representation of a two years' trained tree, with an equal number of shoots on each side, and one going erect. On this upright shoot the cultivator must depend for furnishing the tree. The matter of first importance in the management of this espalier is to abstain from pruning the first season after planting. The cultivator will then probably find this central branch somewhat long and unruly; but never mind, that the knife will set to rights the next winter, if used by a skilful hand, and it will better bear it than at the time of planting. Probably, during the summer the tree may make a little breast-wood, which must be taken off about the end of July, or even a fortnight later will do no harm in strong soils, as the tree must not be allowed to exhaust itself in making useless wood. This, however, it will

do if the foreright shoots are taken off earlier, as the buds below the point taken off, instead of remaining dormant, will start again into new growth, when probably they will become fruit-buds if not allowed to grow prematurely. As these remarks are applicable in every way to the summer pruning of the trees in a more advanced state, I would beg the reader to take note of them, and then there will be no necessity for my repeating them again.

Referring to the central branch on the sketch, the cultivator will observe a cross mark, A. This is the point to which it must be headed back the next winter after planting. From the space left below this mark there will most likely push out four or five young shoots early the next summer. Secure, in the first place, the uppermost one to train up as a leader, exactly in the same manner as the one which was headed down. The remaining shoots are to be neatly nailed in at equal distances, to fill up the space on the wall. The points of these shoots, as well as those previously made, must remain untouched, except to be neatly nailed in as they grow, and not until they have extended the whole length they are required to go should they be stopped. But it is not so with the central shoot. This must undergo the same operation of heading down every winter, until the whole space is filled up. It will be understood from this that every year a fresh young leader is obtained by heading down in the winter, leaving five or six buds to break and afford a fresh supply of young wood, until the top of the wall is reached. As to the winter pruning of pear-trees, it is a thing of the past with all those who have a right to be called cultivators. Leave the pinching of pear-trees to those who have nothing better to do, and be satisfied with pruning your trees in the cool evening hours of the departing days of July; and if work presses, do not worry yourself if it is not done before the middle of August. Always prune those of weakly growth first, leaving the most vigorous ones till last, and then, instead of having a second crop of young

wood to cut away in the winter, which you will do if you follow the old practice of cutting them at midsummer, you will have some nice plump buds peeping out as the leaves fall, looking most healthy and promising for a crop the next year.

Very much more might be written, but I must be content with giving the more important details, for I should be sorry for the reader to get weary of the subject; I must therefore close with just a reference to the manner of root-pruning. It must be remembered, then, that this should be done only with vigorous trees that have attained size without any inclination to be fruitful. I lift half of the roots of a tree and cut back the most vigorous roots one year, and repeat the operation with the other half the next; I find this generally to have the desired effect.

Eighteen select varieties of pears for walls.

The following selection consists wholly of good varieties, and is arranged to afford a supply for as long a period as it is possible to have pears in good condition:—

Name.	Season when ripe.
Jargonelle	August.
Flemish Beauty; a fine melting rich pear	September.
Fondante d'Automne; a delicious fine-grained variety, very juicy, with a rich aromatic flavour	October.
Beurré d'Amanlis	Beginning of October.
Duchesse d'Angoulême; one of the largest	October and November.
Brown Beurré; an old pear of great excellence	October.
Beurré Diel	November.
Beurré Bosc	November.
Seckle; this is a well-known kind of great merit	Beginning of November.
Knight's Mouarch; large and good	December.
Jewess; bears a medium size fruit, melting and very juicy	December.
Passé Colmar; produces fine well-flavoured fruit grown upon a wall; when in the open quarters it is sometimes coarse grained	December.
Napoleon; requires a west wall to grow it fine	December.
Ne Plus Meuris; one of the best	January and March.
Marie Louise	March and April.
Easter Beurré; the best late variety	February and March.
Beurré du Ranco	March to May.
Prince Albert	March.

A selection of eighteen varieties for standards.

These will in ordinary seasons produce some excellent fruit, if not planted in an exposed situation.

Name.	Season when ripe.
Alexandre Bivort	December and January.
Williams's Bon Chrétien	September and October.
Jargonelle	August.
Autumn Bergamot, also known as English Bergamot and York Bergamot	October.
Vicar of Winkfield	December and January.
Beurré de Rance	March to May.
Bon Chrétien Fondante	October and November.
Chaumontel	December.
Crasanne; requires a wall in some places, but in the southern and western parts of England bears tolerably well as a standard	November and December.
Knight's Monarch	January and February.
Fondante d'Automne	October.
Gansel's Bergamot	October.
Marie Louise	October and November.
Passé Colmar	December and January.
Seckle	October.
Thompson's	November.
Winter Nelis	January.
Windsor	August.

A SOMERSET GARDENER.

THE NEW HOLLAND PITCHER PLANT.

At page 125 of our last year's volume (says the *Irish Farmer's Gazette*) will be found a notice of a remarkable and interesting specimen of this most singular little plant. The specimen then noticed was remarkable, as being an unusually fine example of a plant which many an expert, with every appliance in his favour, has been unable to grow satisfactorily. It was, moreover, specially interesting as being grown, not in the plant-house, but in the drawing-room window; not in the pure air of the country, but within the precincts of the city; not looked after by the skilled plants-man, but watched and tended by a lady amateur—Mrs. Pidgeon, of Waterloo Road. We allude to it again on the present occasion, by reason of having been to see it within the present week, and finding it in flower, the scape being very strong, from eighteen inches to two feet high, and even promising, if permitted, to ripen its seeds. The climacteric in the room-cultivation of our plant has thus been reached, demonstrating that in every stage of its development it is perfectly amenable to room treatment, and, therefore, about the most interesting thing that one who loves plants, but cannot gratify the love to any extent, can take up, or the delicate invalid look to to relieve the tedium of confinement, or the *annui* of the sick-room. As most of our readers are aware, the interest of the *Cephalotus follicularis* centres in the singular and beautifully organized ascidia or pitchers; the flowers are insignificant. The scape is smooth, somewhat downy, and towards the end the minute saxifraga-like flowers are borne in alternate and rather distant little clusters, quite close to the scape. We are glad Mrs. Pidgeon has allowed her plant to flower, and trust it may be permitted to ripen one or two capsules of seeds, merely to show how amenable it is as a house plant. But, as a rule, we would recommend the removal of the flower scape the moment it shows, as allowing it to grow, flower, and, above all, ripen seed, would necessarily tax the powers of the plant, and militate against the growth of the plant, and development of the exquisite little pitchers, which afford such unflinching objects of interest to the grower, and are the puzzle and admiration of all who look on them.

CULTIVATION OF THE POTATO.

This most valuable of roots was introduced from the colony settled in America by Sir Walter Raleigh, about the year 1586. It is a native of the continent of South America. It was first cultivated on Raleigh's estate in Ireland, but never came into general use until the commencement of the present century. It was considered as a delicacy in the time of James I., for in 1619 a small quantity is mentioned as bought for the Queen's use, at one shilling per pound. They were recommended in 1662 by the Royal Society to be more extensively planted; but even in 1718 Bradley mentions them as a root of little note. Some few years ago I made various interesting experiments upon the manner of growing this root in the kitchen garden and farm of the late P. Pusey, Esq., in Berkshire, a gentleman of great agricultural repute. I was filling the post of gardener to that gentleman, and had an opportunity of watching his mode of culture. I will content myself with giving the mode of treatment which I consider the best. The time of planting depends on the locality and nature of the soil, making allowance for the diversity of climates, &c., and although they have succeeded well from the middle of February to June, yet either very early or late planting ought to be avoided. I will detail a method which, on light soil and in a warm situation, will amply repay the trouble, either for home consumption or with a view to profit. This plan is practised in Devonshire, and many parts of Ireland; it is called the "Lazy Bed" system. It is performed as follows: Mark out the ground four feet and a half for the beds, and two feet for the alleys, then remove about four inches of the surface of the beds into the alleys; afterwards dig the beds, and if the soil is not good in heart, manure must be added under the potatoes, if at all heavy; but if very light, place it above them. By putting manure under early potatoes on strong soil, it acts as a drainage. I always choose good-sized well-ripened potatoes, and lay them in a warm dry place until the eyes sprout a little; when they have done this, cut them carefully. The crown-sets may be kept and planted by themselves; as they contain the best matured eyes, they always rise stronger and more regular than those from the sides. Sets cut from large tubers, each containing one eye, have, by numerous experiments, been proved superior to whole small potatoes. I planted half an acre of potato eyes. The eyes were scooped out of the potatoes previous to taking them into the house, and packed away in coal-ashes till the planting time, but the produce was inferior to either large or small sets. The large potato has a large eye or bud, which remains undiminished in the section composing the set; on the contrary, the small potato has a small eye or bud, from which, in the first instance, only a weak shoot proceeds, whereas the other starts vigorously, producing an early and extensive breadth of foliage, supported on a stem capable of bearing it up in the light, and hence producing better crops than either one weak stem or a quantity of such. In planting the main crops of potatoes, I don't go in for the Lazy Bed system. I choose a dry situation and a light soil in preference to heavy land. In the process of planting, open good wide drills with the spade two to three feet apart, according to the strength of the variety, and plant the sets uniformly six inches deep. Hoe frequently to keep down weeds, and draw the earth over any tubers which may be formed near the surface. There can be no doubt earthing-up diminishes the produce, and retards the ripening of the potatoes. For late planting choose kinds which do not grow very tall or produce abundance of flowers. My favourite potatoes are the following:—

1. Veitch's Prolific Ash-leaved.
2. Soden's Early Oxford.
3. Early Manby.
4. Fortyfold.
5. Bread-fruit.
6. Giles' Seedling, a prolific potato; average, 160 sacks per acre.
7. Lancashire Pink-eyed.
8. Birmingham Prize-taker.
9. Fluke.
10. York Regent.
11. Salmon Kidney.
12. Jersey Blue.

I would offer a few remarks on Veitch's Prolific Ash-leaf. It has the advantage of other kinds: it makes but small haulm, and the tubers are soon ripe and off the ground, to make way for the cabbages and winter greens.

Notting Hill.

WILLIAM GILES.

THE CHINA PEAR.

The pear even in England is generally understood to be a tardy-bearing tree, and the old couplet,

He that plants pears,
Plants for his heirs,

is an expression of this popular belief; nor is the character entirely undeserved, as, with the exception of a few varieties, ten, twelve, or even a greater number of years will oftentimes elapse after the trees are planted ere they bear fruit. Such being the case even where it has been long acclimatized, people are naturally backward in planting it here under new and untried conditions.

But my object just now is not to point out how we shall succeed with European and American varieties (experiments upon which are going on), but to endeavour to direct public attention to the China Pear.

This variety appears to have been in the neighbouring colony of New South Wales for many years. Being struck with the name, as probably denoting that it had been received from China, and knowing how thoroughly all fruits of Chinese origin appreciate our climate, I procured a tree, and, as it was late in the season, temporarily planted it between two rows of grape-vines, on the brow of a schistose slope devoted to grapes. After remaining there two years it commenced to bear, and has borne regularly and freely ever since; requiring generally a little thinning of the crop, as it has a tendency to overbear.

It has had no doctoring and very little attention, except taking out the leading branch to open the interior of the tree, that it might bear on the inside as well as on the outside of the branches. It is grafted on the common pear-stock of the nurseries, has never been root-pruned nor lifted, and occupies a space of about 6 ft. by 6 ft., or four square yards of ground. The wood is a dark gray, sprinkled with white dots, robust, long-jointed, of upright habit, and producing a profusion of fruit-spurs.

Unlike other pears, cuttings readily root, especially if shaded and watered during a dry hot spring, and I feel convinced that it will play an important part both as stock and medium for grafting and double grafting other pears that are shy fruit-producers on the common stock. I have not yet proved

its perfect adaptability to the Quince, but am experimenting with some of the best Flemish and French pears on the rooted China cuttings. The Marie Louise shows a stocky sturdy robustness on this stock that is suggestive of a hopeful future.

The fruit, when ripe, varies in shape, the breadth being sometimes as great as the length. It has a warm yellowish ground, dotted all over with russet; a good-looking and very fragrant fruit. Its flesh is crisp, juicy, and sweet, the skin having something of a musky pine-apple flavour; and as a cooking fruit—baked, stewed, or in pies—it is unsurpassed by any other pear, its flesh when cooked having nothing like lumpiness or grittiness about it—in fact, leaving nothing to be desired. I have not said anything about its keeping qualities, as it has not been tested fully—the kitchen demand is so much greater than the supply. But I kept three or four in the summer of 1865-66 for six weeks on a shelf in an ordinary room, and the inference is that if they had been put away in a dry cellar, or some cool, dry, dark place, they would have been preserved much longer.—FRUCTUS, in "Queenslander," *Australian Paper*.

ATTAR OF ROSES.

The following sketch of the method by which the attar of roses is prepared at Lahore was drawn up after an inspection of the apparatus and method of proceeding employed at one of the largest establishments in the city. It is taken from the columns of *Indian Public Opinion*.

1st. *Flowers employed*.—The petals of the ordinary country rose are generally used (*Rosa centifolia*), and occasionally those of the *Baramasa*, but these are only half the value of the first-mentioned sort; no other kind is found to produce so much or so good an essential oil.

Of these kinds of roses the native druggist believes that about 1000 maunds of flowers are used annually at Lahore and Umritsur, for the purpose of distilling, the price of each maund being from 2 to 3 rupees, according to the season and quality.

The rose petals are used as fresh as possible, and are first carefully picked to remove any dirt, and also stalks, calyx, and stamens.

The apparatus used.—1st. A large copper degchie with a wide mouth, and the body sufficiently capacious to hold 4 maunds of water.

2nd. An earthen flat gumlah employed as a lid; this is perforated with a hole to admit,

3rd. A bamboo pipe joined to the mouth at right angles, perforated throughout its whole length, and secured with a string.

4th. A long copper vessel with a narrow neck, into which the bamboo pipe is thrust and plugged with a cloth. The vessel is put into a cistern and surrounded with cold water. 5th. A degchie with a broad mouth. 6th. A bottle. 7th. A tin cup.

Quantities used.—Twenty maunds of picked rose-leaves, one maund of water, 50 tolahs of *chundun* oil of sandal wood, *Pterocarpus santalinus*.

Process.—One maund of rose-leaves and half a maund of water is put into the first degchie, and the cover and tube fixed on with clay, the other end of the bamboo pipe is inserted into the long-necked vessel, No. 3, into which 50 tolahs of sandal-wood oil is placed, and this vessel is set in the cistern full of cold water. Heat is applied to the bottom of the first degchie until ten seers of water are distilled over into the sandal-wood oil, carrying with them about three mashes of genuine attar of rose, which is dissolved by the sandal-wood oil.

The apparatus is then taken to pieces, and the rose-leaves thrown away. The mixed oil and distilled water are poured into the degchie No. 5, and allowed to stand for some time. The oil rises to the surface of the water, and is separated by a singular but rude process. The operator dips his naked hand flat on the oil, which adheres to the skin and prevents the water wetting it, he then raises his hand and scrapes it on the side of a tin vessel into which the oil falls, and is thence poured into a bottle. This process is repeated till all the oil is separated from the water. Then the process is recommenced, the oil is poured into the vessel No. 5, and the water with one maund of fresh rose-leaves into the degchie No. 1, and the distillation recommenced and carried on in the same way as before.

This process is repeated for twenty days, and though the druggist considers that 3 mashes of pure attar of rose are distilled every day, yet by the clumsy process of separating the oil and water so much is lost that, though 5 tolahs of attar are added to the 50 tolahs of sandal-wood oil, yet only 50 tolahs are produced at the end of the process; so that one part in ten is wasted.

The product sells for its weight in silver, each tolah-weight selling for one rupee.

THE IRONMASTER AND HIS GARDENERS.—The late Mr. Crawshay was exceedingly fond of gardening, and most of the operations carried on in his gardens and hothouses were under his own superintendence. It was a subject of much annoyance to him when his gardeners would not implicitly follow his directions, but preferred putting in practice some theory of their own. "They are so confoundedly conceited," he would say, "one can't get them to do as they are told." Upon one occasion, when engaging a gardener to fill the place of one who had been dismissed for not acting in accordance with his master's commands, Mr. Crawshay took the opportunity to give the new-comer a short lecture, which he concluded by observing: "There, I have told you what to do; but I don't suppose you'll stay here long; you'll be like all the rest, so confoundedly pig-headed and conceited." The man expressed his willingness to follow his master's instructions, and after he had been employed about a fortnight his professions of obedience were put to the test. Mr. Crawshay came into the garden one day in early spring, and, pointing to a row of gooseberry trees, abruptly told the gardener to take them all up, and stick the branches into the earth, leaving the roots turned upwards. "They don't seem to grow as they are," he remarked, "so I'll try my plan." Mr. Crawshay then turned away abruptly, whilst the gardener, without making any reply, immediately set to work. In a few hours the job was completed, and upon Mr. Crawshay returning and finding that his commands had been obeyed, he observed, "That's all right; put 'em back again. I only did it to try ye; you'll do: I believe I've got a sensible fellow at last." [The foregoing is cut from a newspaper, and it may be true.

But it does not, we venture to think, reflect any credit on either master or gardener, but the gardener comes best out of it of the two. The master gave an absurd order, and the man, taking note of his whim, proved himself his equal in wit by what appeared an act of implicit, unthinking, and obsequious compliance. When two people engage in an act of stupidity, it is not a nice question to determine who should have most praise.]

THE AMERICAN BLIGHT AND FOWLER'S GARDENERS' INSECTICIDE.

The various diseases to which the apple tree is subject have occupied the attention and the pens of some of our greatest naturalists, as well as many of our eminent and practical gardeners. Animals of different species prey upon our garden plants, and our endeavours therefore would be in vain if we were to attempt to avoid the blights affecting the leaves and blossoms of large trees, such as the apple weevil (*Anthrenus pomorum*), and the codlin moth (*Carpocapsa pomonella*). The female moths deposit their eggs in the flowers, one in each, which are soon hatched, and begin to feed on the softer parts of the fruit, which causes the fruit to fall off. Now, it is obvious from the habits of these insects that it is not an easy matter to destroy them. But the trunk and branches of apple trees are oftentimes injured, and sometimes destroyed, by pests of a less tangible nature, and perhaps none has done more mischief, or is so hard to be killed, as the cotton blight, a white mealy insect (*Aphis lanigera*), commonly called the "American Blight." This disease makes its appearance like little bunches of cotton wool stuck upon the trunk, and along the branches and shoots. Under this white stuff there are innumerable insects, which, if squeezed, are of the colour of blood. After it is rubbed off, little round pimples or lumps appear, which are very unsightly. This blight was first observed in the neighbourhood of London; it is supposed it was imported from France in the year 1788. It becomes winged in July and August, and spreads itself from one tree to another, and has now made its way into every county in the kingdom. Some say it attacks the roots as well as the branches; but this I never found to be the case. In the gardens that I have recently taken charge of, I found this pest had got complete possession of all the apple trees, and some were thereby rendered useless. Of course I had heard of, and had seen tried, and had tried myself, various means of destroying this pest. An Irish gentleman recommends the water that potatoes had been boiled in as a certain cure. Another says, rub green mint on the affected parts; this applied perseveringly entirely cures the worst tree of this disease. I think the cure consists more in the mechanically rubbing than the green mint. I have found Gishurst Compound, of the consistency of paint, a capital remedy when rubbed on the tree with a good stiff brush. If it does not destroy them at once in their operation, it gives them an uneasy life, and stops their ravages. So numerous are the nostrums for the cure of blight, and such high authorities speak in their praise, that if I have tried any of those remedies it has always been with caution, never forgetting what I heard Mr. Gordon once say to Mr. Spary, when he was explaining how destructive his patent fumigator was to all kinds of insects. "Ah," says Mr. Gordon, "perhaps it will kill plants as well, for the fumes of your apparatus are like the quack doctor's physic, for he gives them all the same dose; and what cured a tinker killed a tailor." So it would be in a house of mixed plants; some it would kill, and the strong it might cure. Now, without any more beating about the bush, I will speak of the new Vermin Killer. Well, I procured a jar of what Mr. Fowler calls "Gardeners' Insecticide." A very scientific name this. Ah, we gardeners like long names; we should not care whether it was insecticide or infanticide, so long as it killed all our enemies. I dissolved four ounces in a gallon of soft water made hot. When it cooled down to 85°, I took it to some dahlias the blooms of which were infested with thrip. It destroyed them instantly, without the least injury to the flower. Then, for a further proof, I immersed a tender fern, *Adiantum cucucatum*, infested with aphids. The result was satisfactory—the aphids killed, and not a frond injured. I now made the insecticide hotter and stronger—six ounces to the gallon, and the temperature 100°—and went into the orchard, and commenced trying its efficacy on the American blight. I syringed the affected parts, and I have much pleasure in saying that at the first shot I fired with the syringe these tiny vexatious enemies, keeping in ambush behind their bales of cotton, began to disperse in all directions, and the dead and dying fell to the ground never to rise again. I would recommend all my fellow gardeners to keep a constant look out for this American blight; it requires a quick eye and constant observation to detect the first colony of foes. Now that we have a cure of a comparatively inexpensive nature, let us try our best, and free ourselves from this troublesome pest. N. COLE.

AUXILIARY BOILERS.

A correspondent, H. Henry, asks if an auxiliary boiler is required in a case where cucumbers are grown through the winter, vines started at Christmas, and strawberries, French beans, &c., in January. He has eight houses to heat, one of them a peach-house adjoining the vinery, where the heat is put on in the middle of February, and other forcing houses, as above stated. Without doubt an auxiliary boiler would be a safeguard where forcing to the above extent is carried on; but increased experience in this matter convinces me that it is a mistake to put up two large boilers of the same size in places where there is not a greater range of glass than in that of our correspondent, especially when the forcing is confined to one or two houses for three or four months of the forcing season, as in the case now under consideration. Cucumbers for the winter, and vines at Christmas, in two small houses, in which are also grown strawberries and French beans from January, is not sufficient work for a large boiler, although later in the season, when the peach-house is added, there may be, as also would be the case in frosty weather, when the other houses required heat. But to have to heat, say a 4 ft. saddle or cannon boiler for two small houses for nearly four months is a great waste of fuel, because a boiler of less power, and requiring less firing, would answer quite as well. To proportion the size of the boiler to the work it is required to do, should be the first aim of those who have the management of it; and as auxiliary boilers are only put up as a safeguard against a break-down with the permanent one, I maintain it will be a great saving if we consider them both as permanent ones, only using the small one when there is the least work to do, and the larger one when the houses are all in full work. By this plan not only will the expense of firing be diminished, but there will be less chance of an accident from boiling over, as the larger the boiler the greater the body of fire; consequently there is more risk attending its use when its work is of limited extent in comparison to its size.

Against the adoption of small auxiliary boilers it may be urged, that they would not have sufficient power to be of much use should the larger one at any time fail. But against this I must demur. A 27 in. saddle or cannon boiler would keep seven or eight moderate-sized houses free from harm until another larger one was supplied, should anything happen. At all events, my advice is (what I should now practise myself), put up one sufficient to

work the whole, and a smaller one to do the work of the two small houses for cucumbers and vines from the beginning of November to the middle of February, only using the large one when the weather demands it, and, according to the price of firing within twenty miles of London, there would be a saving of from three to four pounds a year in the item of fuel.

On the subject of boilers and the heating of garden structures generally, there has been much useful discussion in these pages from time to time, in which I have been very much interested, and I am therefore sanguine that our readers will not lose sight of the subject, but continue to ventilate the question of heating until we have gained a thorough knowledge of all its features; for I am satisfied from common observations that we have much yet to learn, and the sooner we can do this the better for us and our cause, to say nothing of posterity.

J. C. CLARKE.

DALECHAMPIA ROEZLIANA, V. ROSEA.

Amongst the many meritorious novelties of the past season, none is more deserving of the attention of cultivators than this beautiful Mexican plant. It was first met with in Vera Cruz by Roezli, and, according to the absurd practice of naming plants after persons, it bears his name for a specific distinction. It is a member of the vast order Euphorbiaceæ, and belongs to that section of the order the plants of which have broad cotyledons. The genus Dalechampia is characterized by the presence of a single ovule in each compartment of the ovary, by the anthers being erect in the bud, by the segments of the calyx in the male flowers touching their margins, and by the two-leaved involucre enclosing flowers of both sexes. These involucre, or, as they will no doubt be more commonly called, "bracts," are in the plant before us of a bright pink colour; the male and female flowers which they enclose are yellow. As respects the peculiarity of its decorative features, therefore, this plant may be classed with the Bougainvillea and the Euphorbia, in both of which the most highly-coloured portions are not the true flowers, but their appendages. There are two varieties of Dalechampia Roezliana, one with green, the other with pink bracts. It is the last-named that we especially recommend to the favourable consideration of cultivators.

One of the most interesting features in the numerous admirable exhibitions of the plant by Mr. Bull, of King's Road, Chelsea, during the past season, was the perfection in respect both of leafage and richness of floral colouring of the very small specimens that were brought forward. It does not need a vast extent of space, or a great length of time, to grow this plant to perfection; indeed, it blooms freely in a small state at every period of the year, and the coloured bracts are so persistent that the plant retains its brightness of colouring for a great length of time. In habit it is an erect-growing under-shrub, with sub-cordate or spoon-shaped acuminate leaves, five to nine inches long; the stem is clothed with egg-shaped stipules; the peduncles are slender and thread-like, bearing two small green bracts and two large cordate denticulate floral leaves of a bright pink colour. Within these are the male and female flowers, of a pale yellow colour.

This is a highly ornamental plant, which may be grown to a large and grand specimen for the stove, or flowered in a small state for the decoration of the table. As it can be flowered at any season, it may be added to the list of select winter-flowering plants; for at this season of the year its gay bracts will be of far greater value than at any other time. As a winter-flowering plant it will need the stove, yet it may certainly be grown and flowered successfully with only warm greenhouse treatment, as, though a stove plant, it happens to be well adapted for what is termed cool treatment.

BATHING IN LILIES.

Once upon a time, Mr. Editor, in the spring of the year, when the spring flowers were full of glory, you kindly informed me by letter that you contemplated being from home for a few days; in fact, that you intended to go down to the New Forest to bathe in violets. I remember I wished you a safe and a pleasant journey, but I did not confess at the time that I felt you were tantalising me, for I was necessarily tied by the leg at home, being in the midst of a forcing season, and therefore could not go with you, had I wished, or had you invited me. I felt that you knew this, and I considered that you ought to have had more consideration for my position than to have broached the subject to me, knowing how much I liked such rambles as you contemplated taking. In fact, I felt that you might have gone and enjoyed yourself, and then informed me of it if you pleased, instead of filling me with longing. However, in contemplation of revenge, I pocketed your letter, determined next time I was about to enjoy a treat to apprise you of it, so

that you might have a fellow feeling, and be more discreet in the future. But, upon more mature consideration, I relinquished all ideas of tantalising you, as you had done me—in other words, I would not return evil for evil, but prefer to tell you after my joys are over, and I hope for the future you will take the hint, as far as concerns me, and do likewise.

But you will be asking, "What has all this to do with Bathing in Lilies?" Let me tell my little tale. You go some forty or fifty miles, with danger before you with every turn of the wheel, to bathe in violets, while I stop at home to bathe in lilies. Ah! and in beautiful lilies too, such as are not seen in every nobleman's garden, although a cottager may grow them. Perhaps now you may condescend to ask, "What are you driving at?" or you may be a little bit starchy, and say to yourself, "Why, the old man is a ninny to think I never saw a lily." But I do not think so, for I know you have seen many, but I question if ever you saw a whole batch of the common Guernsey lily, with about fifty spikes of bloom on them at one time, in the middle of October. Such was my lily bath lately. Many of the spikes contained five individual flowers, and some of these measured four inches over, standing boldly up about twenty inches high upon stems thicker than a man's thumb. Imagine all these making a solid mass of colour in a small space, and you have an idea of a splendid scene. It is many a long day since I saw so beautiful a sight as these lilies created.

Now, tell me if you have ever seen the like. I do not want to hear of an individual spike or two, such as is commonly seen, but from forty to fifty spikes, each with three or four flowers open at one time, standing close to the front wall of a vinery, about 30 feet long. I think you, with all your experience, will be obliged to answer no; for I have travelled a good deal, and have never seen anything like it in the way

of lilies, although I have seen many wonderful horticultural sights, but not one with such a peculiar richness as this. The term "gorgeous," in its literal sense, is not applicable to this mass of floral beauty, it was so rich and chaste; while the natural bearing of the flowers was so grand, with such a delicate touch of refinement about them, that, in a word, it was the most lovely sight that ever pleased horticultural eyes. But do not think the old man is vain because he possesses such rare treasures of Flora's empire, or that he wishes to retaliate upon you in an unseemly manner. No, no; his principal object in writing this is to let your readers know that the lovely Guernsey lily is still cherished by one who is somewhat alive to the beauties of the hardy border plants, of which this is so excellent a member. Changing back to the first person, I wish to say that I have now good grounds for asserting that I have bathed in lilies.

Now I am coming to the practical; and to show you that I am not anxious to enjoy this treat alone any longer, I will, if you like to accept of a few bulbs, send you some on an early day. All the cultivation they require is to plant them deep in a rich sandy loam close to the foot of a south wall, and leave them undisturbed for the next seven years, and you will get flowers in plenty.

P.S.—This was written a month ago, but got mislaid; all the time I was wondering why I could not see it in print. To-day I have popped upon it, and, although late, I send it on, because I dare say you have been wondering what had become of

THE MAN WITH THE BLUE APRON.

[The Guernsey Lily, *Nerine sarniensis*, deserves all the praise the "old man" has bestowed upon it, but *N. coruscans*, *N. Fothergillii*, and *N. venusta*, are equally beautiful, and perhaps even more beautiful; therefore the "old man" had best add a few clumps of these to his border. If he will send us a parcel of his, we will send him some of the other three kinds in return. Mr. Barnes, of Bicton, could tell us something about bathing in lilies, for he has some long borders filled with these *Nerines*.—Ed. G. M.]

A PROTEAN FERN (*ARTHROBOTRYA ARTICULATA*).

The vagaries of ferns are quite as strange as their mode of re-production. Since the fern mania, and more especially the mania for British ferns, has set in, the latter seem to have run riot in their anxiety to meet the craving for new varieties. In fact, so many forms crop up that to find distinctive terms for them is apparently more difficult than to find the plants, if one is to judge by the vagaries of language had recourse to, to distinguish the varieties of British ferns.

Turning from the cultivated forms of these islands to a singular and interesting species, sometimes grown in choice collections of hothouse ferns, a portion of which is lying before us, we find a curious illustration of the Protean character of these plants. We allude to the curious little Bornean creeping fern, *Arthrobotrya articulata*, or, as it was first called, *Lindsæa Lowii*, by which name it may still be known by our readers. Since we first saw it in one of our finest collections, when introduced some four or five years ago,

DALECHAMPIA ROEZLIANA.

we have regarded it with interest from its singular habit, as well as its rarity and its being considered difficult to keep. It was, however, only on occasion of a recent visit we ascertained that what we had on previous occasions looked on as an interloper in its case, in the shape of another fern as unlike as possible the normal form and appearance of our plant, was no such thing, but part and parcel of the *Arthrobotrya*. This will be better understood by our fern-loving readers from a description, though it be imperfect, of the normal appearance of this wiry little Proteus. The innumerable little creeping stems are dark, wavy, thin as finest wire, and furnished along the lower surface with a line of clasping suckers like those of the ivy, by which it fixes itself in its rambles over the tufa, or other surface upon which it grows. From these stems at right angles, and plane with the surface on which they grow, proceed neat little pinnate fronds, not unlike those of our own little *Asplenium trichomanes*, except that they are much smaller, more compact, and the diminutive pinnules more crenated. The fronds are about three inches in length by half an inch in breadth. The pinnæ are about a quarter inch long, less than that broad, and roundish.

Now for its anomalies. Some of the fronds, eschewing the original or pinnate form, have the pinnules or leaflets only on one side; others have one side fully clothed and the other side bare, except a small portion near the top. Other fronds show the dichotomous character, or tendency to fork, which appears to be the first freak when a fern is about to put on a new "make up." These, however, are trifles compared with the next jump our Bornean friend takes, when from the extremity of one or more of its living wires it sends forth apparently another fern, about as unlike itself as another fern could be. Compared with the parent, this is a giant, the fronds being like the exotic *Doodia caudata* in appearance, and almost as large, or, to take a more familiar illustration, in size and form like those of our own *Blechnum spicant*. The frond before us is more than eight inches long, by $2\frac{1}{2}$ inches wide. The pinnæ are placed alternately and rather distant from one another, oblong lanceolate in shape, perfectly simple at the edges, fully an inch and a half long by half an inch broad, the colour a much paler green than that of the normal leaflet. A good general idea of the appearance they present, and the remarkable departure from the original form, may be had if the reader call to mind what we so often see occur in the fern-leaved beech. When first introduced, if we remember rightly, Mr. Smyth, of Kew, regarded the original form as being only the imperfectly developed form of a plant which in its adult state is quite different.

We regard this as a very interesting fern for growing in a case, if it would accommodate itself to the temperature of our rooms. This difficulty might, we fancy, be overcome by a little ingenuity and thought. If so, our Kilmarnock favourite would have a rival, and the dwelling-rooms a new feature, which would have interest for all, and be one of priceless value to the confined invalid or the aged, who know no world outside it.—*Irish Farmer's Gazette*.

Calendar.

WORK FOR WEEK COMMENCING DECEMBER 7.

Kitchen Garden and Frame Ground.

CABBAGE, SCOTCH KALE, and other standing vegetable crops should be lightly hoed between when the ground is dry, and the plants earthed up; this protects their roots from frost, and supports them against wind; and the hoeing removes weeds, and by loosening the top crust prevents frost entering so deep as it does in hard ground.

CAULIFLOWERS, LETTUCES, &c., in frames and handlights must have plenty of air while this mild weather lasts, by removing the glasses entirely on fine days, and keeping them tilted during rains. If any signs of mildew, sprinkle with sulphur; the *Boite à Houppes*, sold for half-a-crown by Burgess and Key, Newgate Street, is the best sulphur duster, and should be always at hand in a dry place ready for use. It delivers lime, sulphur, or any dry powder in a regular cloud, and is very expeditious. The fine dust from the bottom of the peat-stack or the bins of the potting-shed will be found useful to strew on the surface amongst plants suffering from damp; there is nothing to equal peat-dust for the purpose.

PEAS AND BEANS just showing through the ground should be covered with a sprinkling of dry earth, and over that some dry light litter; this will check their growth and keep them hardy, and in case of frost afford considerable protection. Where sand is plentiful, use it in preference to mould, because of its drying nature.

RHUBARB AND SEAKALE.—Those who have not begun to force should do so now, either in the open ground or by potting. As a very mild heat suffices, this season's leaves and litter, if plentiful in bulk, will do as well to make up a bed for the purpose as dung. If the latter is used, it should be turned three times before making the bed, or the heat will be too fierce and too transient.

Flower Garden.

EVERGREENS are generally planted at this season, because alterations are in progress, and it is found convenient to plant all at once—deciduous and evergreen trees together. But we question the propriety of moving any evergreen shrubs from November to February. We have always advised planting hollies, aucubas, bays, &c., &c., in August and September; and if no moved then, they had best be left where they are till March. Nevertheless, it is often convenient to lift evergreens now, and almost everything except the holly will endure the process if it is performed with care. On wet days there is more likelihood of deaths occurring through removals now than on warm dry loams. We have ourselves been compelled lately to move some very large specimen evergreens, and we took care to close in the roots with a mixture of leaf-mould, fine loam, and sand, in a nearly dry state, so that the wounds of the roots will be encouraged to heal quickly, and at the first move they make they will run freely into the tempting mixture. Where it is intended to plant in spring, let the ground be deeply trenched and laid up in ridges to pulverize.

Fruit Garden and Orchard House.

PRUNING of standard trees should consist chiefly of opening out the head and regulating the growth, without severe measures of any kind. Where large boughs require removal, it is a proof of neglect of some kind in times gone by; and if many large branches are dead or dying, depend upon it the tree is in a bad state at the root: most probably the surface roots are gone altogether. In small gardens, old fruit-trees are frequently killed by raising the soil about them, and so year by year removing their roots farther and farther from the atmosphere.

ROOT PRUNING, where required, should be commenced without delay. The simplest method is to open a trench on one side of the trees, and cut back the roots to within two feet to three feet of the stems (according to the size of the trees), half round each tree. Next year open trenches and cut back the roots on the other half round, and so on year after year. This will prevent a rank growth, and increase their fruitfulness.

Greenhouse and Conseratory.

CALCEOLARIAS, ROSES, PANSIES, and other nearly hardy plants, of which cuttings were put in late, may now be potted off singly while the weather continues mild. This will relieve the pressure of work at the turn of the spring, when there is so much potting to do that other important tasks are neglected.

STOVE PLANTS THAT BEAR COOL TREATMENT.—The idea of "naturalizing" plants from the tropics has long been exploded; but, like the search of the alchemists for some principle which should transmute any and every metal into gold, this idea has unexpectedly been the means of leading us to the discovery of much of which we can make practical use. Our stove plants are no harder now than they were fifty years ago, but we have learned much better how to cultivate them; and one of the lessons we have learnt is, that at certain seasons of the year, and under certain circumstances, they will bear a much lower temperature than had been anticipated. In a word, all plants require a season of rest. Allow them to hibernate for a time, and then when you rouse them up once more they spring into existence with renewed vigour. How many plants we can recall which we at first stewed and parboiled in our stoves! soon they were moved into a warm corner of the greenhouse, and then, having overgrown the space allotted to them, they were some lucky spring morning planted in a warm corner out of doors, just to take their chance. With what result? Why, they perfectly astonished us with their wonderful growth; they had at last been treated in a manner which suited them. I could spread out this paper to any extent by giving illustrations of this. I might give instances from the plants which were introduced years and years ago, such as the *Aucuba* and the *Lycosteria*, and might bring my observations down to the present day by giving some of the results obtained this very year in the sub-tropical department at Battersea Park. One great lesson we have learnt is, that many who from not possessing a stove may have considered themselves unable to grow foliage plants, may now take heart, and compete with their more fortunate neighbours. We would simply throw out a few hints, leaving our readers to act upon them as circumstances shall allow, and hoping to hear of their success next season. Few gardens are so poor as not to possess a littleinery, which is started early in the spring; or if noinery, there is at least a good hotbed. With these appliances much may be done—many novel effects produced in summer, and much additional interest given to the garden. We shall confine our remarks to the growing of foliage plants in pots, not venturing into the wider subject of grouping them in beds out of doors. First of all, we come upon a set of genera which will bear drying off in winter; these are particularly useful in small gardens, where space (as it sometimes is in the largest gardens) is very scarce in winter. Everybody who can grow *Achimenes* and *Gloxinias* may venture upon *Caladiums* with the same kind of treatment. In either case, the roots must be kept dry, and not allowed to feel the effects of frost. How much cold they will really bear without injury is a question very difficult to answer; a small amount of cold accompanied with moisture would do far more injury than a greater degree of cold when they were quite dry and at perfect rest. This is, therefore, a point upon which we may expect differences of opinion. This one genus, *Caladium*, throws open to us at least a score of varied and most beautiful plants. All that would be necessary for them would be a good start in ainery or hotbed in the spring, and protection from cold draughts in summer. There may be—I do not say there is—an exception in the case of the lovely little *C. argyrites*. I have found that it does not absolutely require the same amount of rest as some others; most of them give unmistakable signs when they want to retire for their winter's sleep. There is no doubt but that the coloured *Begonias* enjoy a stove temperature; but may they not be coaxed into doing without it? There is good room to believe they may. Old plants—be careful to note the word "old"—old plants may safely be dried off for the winter. I recollect some years ago having a few old specimens for which no space could be found; they therefore took their place beside the dried roots in a dry and cool corner. They were watched, and from time to time the leaves which were going off were cleared away; in the spring they were pulled to pieces, and the healthy growing points selected for the formation of new specimens. The success was so great that this was made a precedent for future years, and much younger plants went safely through the ordeal. I have safely sent the dried rhizomes of these *Begonias* to friends in the colonies, both east and west. By-the-by, *B. discolor* (or as it is sometimes called, *B. Evansiana*) is a genuine greenhouse species, goes naturally to rest every winter, makes a capital edging for a hed out of doors, and may be propagated to any extent. Will nobody bring it out as a bedding plant at a trifle per hundred? Some years ago, I dare say you grew, as I did, the rice paper plant (*Aralia papyrifera*) in the stove. It was just sent home by Fortune from the island of Formosa; what further proof did we need that it required a high temperature? The plant grew well, made magnificent leaves, and flowered; but it was terribly subject to the mealy-bug—what a job it was to keep it clean! You may generally paraphrase the expression—"This plant is infested by the mealy-bug," by "This plant wants a cooler place;" or else it has been pot-bound, or ill used in some known or unknown way. We had to learn by experience, but it is dangerous work to experiment upon a plant worth four or five guineas, as that *Aralia* was then. It flowered, as I said, and next season we had scores of seedlings. One or two found their way into the bed out of doors reserved for odds and ends. They grew splendidly, and we saw no more of the mealy-bug. If you want to see how it succeeds out of doors, go to Battersea Park in the autumn and enjoy an astonishment. There can be no doubt it is nearly hardy; that the roots, at least, will escape injury, even if left unprotected. At any rate, under cool treatment, and not allowed to be starved in its pot, it will make a glorious foliage plant. There are several other species of *Aralia*, introduced by M. Linden from New Caledonia, which may help to make up a cool collection of foliage plants. That beautiful plant *Cordyline indivisa*, introduced by Messrs. Lee, from New Zealand, requires of course nothing more than the accommodation a greenhouse may afford; and the same may be said of many other allied species. When we come to look the list over, we find many foliage plants which may, with the help of a hotbed in spring, be exhibited in competition with the truly stove plants, when the advantage will not be all on the side of the latter. Let us see how our list would stand: *Caladiums*, *Begonias*, *Cordyline*, *Aralia*,

Cannas, Ricinus, Dracæna (several New Zealand species), *Cycas revoluta, Dasylyrium*, and a good many others in the *Aloe, Agave, and Bonapartea* line. Though there is much we hope and expect may be done under "cool treatment," yet there are some plants which we may expect will hardly put up with this. Among these we must class *Cissus discolor*, which cannot be grown in too hot or too moist a house, nor can it be shaded too much. If you want to see the velvet leaves of this plant in perfection, you cannot overdo either of the three things mentioned—shade, heat, and atmospheric moisture. The same thing may be said of *Alocasia metallia* and its allies, but I am almost afraid to speak about this plant, for I was on good authority told the other day of a plant which had done duty in a seedman's shop for six weeks, and then stood out of doors for ten days without being injured or looking the worse for it. We have much to learn upon this subject, and every gardener who can help us to a fact he has himself proved, will help on the good time coming which will produce another great change in the fashions of the garden world.

Stove and Orchid House.

STOVE PLANTS at rest may suffer if allowed to get too dry, especially those having porous foliage and soft stems. In giving air, take care not to expose tender plants to cold draughts; in fact, air should never be admitted in a volume at this time of year. The general collection of stove plants will be satisfied with a temperature of 60° by day and 53° by night. Orchids require a watchful eye among them; so many diverse climates are now represented in our collections, that it is no easy matter to keep all at rest together, and it may be better to remove a few that require to be kept growing to the forcing-pit rather than risk the safety of others by too high a temperature.

Forcing Pit.

CUCUMBERS that have been in bearing some time may always be restored to a youthful condition by the use of the knife. If we have a length of lights occupied with bearing vines at this time of year, we prepare for their renewal by opening a trench all round the roots, every alternate plant, at a distance of one foot from the stem. This of course shortens in the roots to that length. We then fill the trench with a mixture of chopped turf, leaf-mould, and rotten dung. There will be new roots formed in this mixture at once, and a week after the operation we cut back the vines to within a foot of the soil, and then take up new runners, and stop and train as before. As soon as these show fruit, the remainder can be dealt with in the same way. They want extra bottom-heat after cutting back.

Correspondence.

FLOWERS FOR CHRISTMAS TIDE.—Shortly the whole world will run riot as it were in the decorative art; lovers of flowers will vie with each other in their best efforts in taste to commemorate that most endearing mystery of our faith, the birth of the Incarnate Word. In this country, for three long centuries, roast beef, turkey, and plum-pudding have had more than a fair share of attention at this holy season. However, matters have taken a turn for the better. No one can have a doubt of the fact that church decoration is on the increase, and that it is receiving that attention which it is so well worthy of. What more beautiful and proper occasion can there be than the coming great festival to bring into use all the beautiful in flowers, arranged in appropriate designs, to typify the devotion of our hearts on the way, by faith, to Bethlehem? Material for this purpose can be produced abundantly and cheaply. Equal effect can be produced with Everlastings as with fresh flowers. How easy it is to grow them! He who loves to cultivate flowers can have no more desirable end for their use. These Everlastings produce in such abundance that a few plants will yield thousands of flowers. Gathering them whilst young to have the colours bright, drying them, and arranging them to fancy, with taste, is a delightful occupation. I send you this day, by rail, two small boxes, carriage paid, to London; one box (the flat one) containing two wreaths, and the other box a small bouquet. Though not ecclesiastical in design, they are appropriate for church-work. The flowers are all natural Everlastings, and the varieties of grass either cultivated or wild. I hope they will be as pleasing to your eye as your excellent Magazine is amusing and instructive to my mind. You will see a difference in the style of the wreaths, one being jewelled, that is, the flowers tastefully mixed, and the other with the flowers and grasses grouped. The hands that made these and the bouquet are no doubt capable of improvement, both as to the arrangement and mechanical mountings, and would be pleased to have your independent opinion and critical remarks thereon recorded in your excellent GARDENER'S MAGAZINE. The flowers and grass are all home-grown or wild. My love for flowers, and their use in tasteful decoration, is my apology for intruding this upon you.

Paignton, Devon.

VIVIAN OSWALD WALMESLEY.

[The bouquet and two wreaths forwarded by Mr. Walmsley are the best examples of grouping everlastings and grasses we have ever seen. They are extravagantly beautiful, and they justify all he says about their suitability for Christmas decorations, and their immense value as beautiful objects, considering how easily they may be gathered or grown. The perfection of our friend's work leaves us but small room for suggestion, but it has occurred to us that several varieties of British ferns, if carefully dried when in their most brilliant tones of green and without blemish by wind, would be very useful to intermix with the flowers, the mere points of the fronds being allowed to peep out amongst them. Then all our native species of heath retain their colour perfectly when dried, and have all the elegance of outline that is desirable for this purpose. And why should we not use any of the greenhouse heaths we can get hold of, especially such as *E. hyemalis*, and others that have small flowers? There is a vast field for the selection of subjects when we have made the most of the everlastings and the grasses.]

THE HEALTH OF GARDENERS.—I read with some concern your statement that there must be something wrong in the atmosphere of the plant-houses at Kew—that those whose duty it is to be much in them were one by one overtaken by illness. It is not at Kew only that cultivators of hothouse plants suffer. I think a simple view of the case is, that the houses are so very hot, and the air outside so very cold, that the lungs cannot bear the daily or hourly transition from the one to the other. Now the season which greatly increases this danger has returned, and I hope a word or two may be useful. I myself have frequently suffered from colds caught in this way, having to turn out late on a cold winter night, and run a couple of hundred yards to attend to the fire and return. But, of course, the danger is indefinitely in-

creased when it must be borne at any or all times of the day or night, and, of course, no weak constitution can bear it. Now why do not the gardeners so exposed wear some sort of respirator, which they can put on whenever they go out? I am sure that nearly all the evil consequences would be thus avoided. Almost any sort of a thing will do, provided it be large, thick, porous, and light, all which conditions are easily attained in a kind of respirator which I only heard of for keeping London fogs out. It is simply a little apron, about six inches square (if it is larger it will do no harm), the material to be good stout baize. It is, of course, tied round the head, so as to cover the mouth, which is generally sufficient, but there will be no trouble, if need be, to tie it over the nose also. Besides this, if you do not feel it worth while to make such a contrivance for use, you may just hold your coat-sleeve to your mouth and face, which will answer nearly as well for the time, and I am sure that the benefit would be worth any amount to those who are thus susceptible. I hope these few words of mine may be of use, and I feel sure that no one who tries the thing will fail of a great benefit. It is especially important that cultivators of orchids should be careful of their health, for they are exposed to great risk at this time of year.

Chiswick, W.

A. DAWSON.

SUGAR PEAS.—Referring to the GARDENER'S MAGAZINE p. 492, I notice that you boiled the varieties of *Sugar Pea*. In this neighbourhood we pickle them, just in the same way as French beans, and think them excellent. The best are the tall-growing large-podded varieties.

THOMAS PIERPOINT.

Warrington.

Literature.

The Floral World for December contains articles on the Chrysanthemum in 1867, the management of the villa kitchen garden, the varieties of raspberry and blackberry, the preservation of greenhouse plants during winter, the cultivation of cacti, the preservation of fruit, the centigrade thermometer, and other matters of immediate interest and importance.

The Intellectual Observer for December contains an elaborate paper on the eggs of insects, by Mr. Jabez Hogg; a most valuable and interesting paper on rain, by Mr. R. A. Proctor; a continuation of Mr. Jewitt's gatherings from the grave-mounds of Derbyshire; some biographical memoranda of Sir Isaac Newton, by Mr. Joseph Newton, of the Mint; and shorter papers on the white ants of India, fur-bearing foxes, the structure of annelids, &c.

Replies to Queries.

Physiology of the Tulip.—C. J. H.—The changes that take place in bulbs during the time they are apparently dormant are pretty well known as to their leading features, but have certainly not been studied with the care and earnestness they deserve. In all the literature of horticulture, we remember nothing pertaining to the subject equal in interest and value to what is said in Mr. John Slater's "Amateur Florist's Guide;" yet the subject should be attractive alike to the botanist, horticulturist, and the man of universal science, who cares nothing for specialities, for it promises to unfold to us some of the mysteries of life. The following is Mr. Slater's article on the subject: "The tulip has been cultivated for upwards of two centuries, and notwithstanding its peculiarities none have ventured to analyse it; and although the *why* and the *wherefore* is known respecting nearly all varieties of plants in cultivation, yet in the tulip all is dark and obscure. It replenishes itself every year by making a new bulb, and contains its increase within the folds of skin, as well as occasionally on the outer cuticle, and it is wonderful to watch its onward progress. It is found, upon examination, that the bulb of the tulip does not remain dormant when taken up, but is gradually making progress; and the assertion that the flower bud is made before the foliage lies down is proved by ocular demonstration to be false. Cut a tulip bulb in July, and you will not perceive the slightest appearance of either the new bulb or the flower bud, but about the second week in August some progress will have been made. The germ is then small, only one-eighth of an inch in circumference and three-sixteenth parts of an inch long. In September (the 20) the germ will then be nearly three-fourths of an inch long, and three-eighths in circumference, and the flower bud perfectly formed, and one quarter of an inch long. The appearance of the skin next the germ is quite white and of a woolly appearance, caused, no doubt, by the juices of the skin next the young bulb having been absorbed in nourishing the new growth, and contains scarcely any moisture, and is like the pith of a branch of elder or a rush when cut up the centre. In October the whole of the petals, stamens, and flower stems are formed, and measure one inch long. From this period to March very little progress can be seen, but at the latter end of the month the two outer skins of the bulb will be decayed, and the germ of the new one at the base of the flower stem will have increased to about one-twentieth part of the size of a blooming root, and no stamens as yet perceived. In fourteen days, from this period, not only will the stamens be seen, but also a streak of black up the centre of the anthers, which no doubt is the formation and concentration of the colouring matter for them; after this the stamens gradually increase from one-sixteenth part of an inch to nearly their full size. In thirteen days from (April 13 to 26) the beam in flamed flowers shows itself, and the anthers have then assumed their natural colour; yet the stamens are only one-eighth part of an inch long, whilst the anthers have been from October their natural length, and perfectly white; and the new bulb is one inch and an eighth long, and two inches in circumference. The bulb grows rapidly when in bloom, and still more so after the flower has been cut for exhibition, or when decayed and cut off, and the whole of the five circles of skin have become totally decayed, and the flower stem which was in the very centre of the bulb is now outside. I have now given the progress of the tulip bulb, flower, &c., but the most important and most mysterious operation which nature performs, by the transfusion of colouring matter into the petals, is what we all feel much curiosity to ascertain. I have never read of any botanical writer who has ventured an opinion on the tulip, and it is highly necessary that all should endeavour to ascertain, by actual experiments, how, and in what manner, and when, this colouring matter is infused into the petals. For this purpose a powerful microscope is necessary, and a number of bulbs planted, and at stated seasons examined. It is rather singular that the stamens should not be seen for many months, whilst the anthers are of their natural size in October, and, as I previously observed, a streak of black is seen up the centre of the stamens. As soon as nature has performed this operation, the stamens grow rapidly, and it is very

probable that the colouring matter has been thrown into various portions of the flower whilst the stamens were not perceivable, and after this act, then the communication is immediately cut off, and the stamens elongate. The tulip petal consists of two skins and a fleshy substance between them, and in a byblomen is quite white, so that the outer and inner skins must be perfectly independent of each other, and each have its separate vessels containing colour, or else why should the outside of the petal of the flamed flower be much more correct in its distribution of colour than in the inside. It will often be seen that the inside has a much greater mass of colour than on the outside. The ground on the outside will be seen in beautiful stripes in the feathering, whilst in the inside one it will be nearly a self colour, and very little ground. The same will be observed in a feathered flower. A question that wants solving is, how does the colouring matter get to the edge? Is it by veins and arteries, similar to those in our own bodies, all united and serving as conduits to conduct the colouring matter to its proper place, or is it conducted by little cells of colouring matter all connected together? This last appears probable, from blotches of colour being in the centre of the petal, which the rays of the sun has caused to flow similar to sap in trees, and a cold night coming on has completely stagnated this colour, and consequently it has become a blotch by the communication being cut off. I once observed in my offset bed a singular thing which may serve to elucidate this suggestion. One frosty night the foliage was discoloured by the action of cold, and on the rays of the sun shining upon them, the foliage assumed the appearance of hemp with its numerous fibres in a state of decomposition. This arose from the sap having been frozen, and upon thawing, it burst, thus cutting off the very means of conveying nourishment into the foliage. There is some analogy in this to what I have before suggested as to colour, the vessels containing colour having been frozen, no warmth will cause it again to become fluid. We all know that if the beds are kept at night warm by covering, so as to exclude frost, the marking of flowers is much more correct. Another very important suggestion arises,—is the colouring matter in the petals in October, or at what period does it get into them, and from what source? It is a singular fact that a bud of a tulip was partially cased in the foliage until the latter end of April, and when the foliage was disengaged nothing unusual could be seen, yet, strange to say, the foliage which had touched the bud coloured as the bud coloured, and eventually was as dark as the bloom, only on a green ground instead of a white one, and as perfect a *fac-simile* as if an impression had been taken from an engraved copper-plate. Now it is evident that the colour must have exuded from the skin of the petals, or else it could not have left an impression, only so far as it had come into contact. A carnation petal will, upon examination, be found to be similar to the tulip, a white fleshy substance being between two skins; and as a proof that the colouring matter must be very slightly protected, the colours will run in wet weather if not covered with something to prevent the rain falling on them. It is extremely probable that the colouring matter rises from the root and flows up the flower stem to the bud, and there divides into two channels, one to supply the outer portion of the bud, and the other the inside one. If this were not the case, how does it happen that there is generally more colour in the inside than on the outside? Again, if there are veins in the fleshy intervening substance, it would naturally be supposed that the colour would be equally distributed instead of being so unequally. In some flowers large masses of colour are found on the centre of the inside petal, as in *Catafalque Supérieure*, *alias* Rising Sun, which, after a few days, nearly become a self colour. I once noticed a very curious circumstance in a San Joe, *alias* Captain White, which opened almost a self, but in a few days it was pretty generally feathered. This must have arisen from the colour not having flown into the receptacles at the proper period, perhaps from the coldness of the atmosphere. That the stamens are not conductors of colour, is evident from their being the same colour throughout—if in a bizarre, yellow—a rose or byblomen, white,—and the tinge which is sometimes seen on the top of them is only slightly or thinly spread on them. Take a knife or other sharp instrument and scrape one, and you will soon come to a pure white or yellow, which is a convincing proof that in a majority of cases it arises from the pollen running down upon them, which, taking a portion of colouring matter with it, discolours the stamens to a certain extent, the same as perspiration in running down a person's face, not over clean, shows a channel which gradually assumes its natural colour as the moisture decreases; the same in the tulip, the colouring is heaviest at the top and gradually shades away."

Orchids in Wardian Case.—J. M.—The best orchids for a Wardian case are *Lycaste Skinneri*, which produces large flowers finely flaked with crimson; *Barkeria elegans*, elegant spikes of lilac flowers; *Sophronites grandiflora*, pretty deep red flowers; *Epidendrum vitellinum*, brilliant orange-red flowers; *Goodyera discolor*, the leaves of which are extremely ornamental; *Huntleya marginata*, pinkish purple and white; and *Cypripedium insigne*. Many more may be found, but we should give these the first place in the list of desirable species. We think your plan worth a trial, if the case is kept in a warm room all the winter.

W. R. H.—Your plan will answer admirably. A B C D being on a lower level than the span is an advantage; the tank being above the general level is another advantage.

Amaryllis.—Anxious may start these at any time after they have had some amount of rest. The routine cultivation is of the simplest character. Shake all the old soil from their roots, and repot in the best mellow loam you can procure, with an equal bulk of rotten manure, but without sand or peat, both of which are useless to the roots of *Amaryllis*. Complete drainage is most essential. When the potting is completed water moderately, and place them in a warm house in the fullest light; thereafter treat them generously until the leaves begin to turn yellow, and then gradually dry them off.

Asters for Exhibition.—S. E. A.—The best are the French, the German, and the cockade asters.

Azalea Propagation.—M. E. H.—Very many of the choice varieties are propagated by grafting, for which purpose seedling stocks are grown in quantity. To increase them by cuttings, take the young shoots when they have just finished their growth but have not begun to get hard; cut them into lengths of 2½ inches each, remove a few of the lowest leaves and insert them firmly in sand, and cover with bell-glasses; keep them moist enough to be always fresh and no more, and on a gentle but steady bottom heat, and every one will root. The only matter of importance is to take the cuttings at the right moment; if too hard or too soft, they will not strike.

P. S.—What you refer to is of no consequence to the sense at all; it is a whim of the writer; those who can read it enjoy it, and those who cannot are none the worse off.

The Fall.—R. W., of Birkenhead, asks what is to be understood by the phrase "late in the fall of the year," and presses for a reply on the ground that the meaning of the phrase is a matter of dispute. Well, it is not without interest, perhaps, to some besides the disputants. As a rule, the term

"fall" is not used in this country. It is an Americanism, and the equivalent there of the word 'autumn' here. Supposing the Americans borrowed it from us (as many of their phrases are borrowed without our knowing it), we refer to Bailey's dictionary and find no entry of it there. Hence we conclude that "fall," as the equivalent of autumn, is not an old English phrase. None of the modern English dictionaries have it, but it may be in Webster, which we have not at hand to refer to. It has no place in Todd's Johnson, nor in Richardson's dictionary. We are compelled, therefore, to receive it precisely as used by the Americans, and with them it implies the season when the leaves fall, when the sun declines, when the temperature decreases, when the year is wearing out. But, so far as we understand it, the winter is never designated "the fall;" therefore late in the fall must be just that period of the year when autumn is ending and winter is to be expected. If the term is used here, we should expect it to be applied to the latter part of November, as the leaves are then down, and we usually have frost and snow, and other signs of the real commencement of the winter. If understood as applying to the end of the year, the term is ridiculous; for why say "fall" when "year" would be more expressive? The last week in November we consider to be late in the fall, and the first week of December beyond the fall, and never to be understood by such an expression. Since the foregoing was written, we have been favoured with the following references, for which we have to thank the printer: "AUTUMNUS . . . Autumn, the time from the 6th of August to the 6th of November; *the fall of the leaf*; the season of the year opposite to spring; the time of harvest and vintage" (*Littleton's Eng.-Lat. and Lat.-Eng. Dict., circa 1736*).—"Fall . . . automne" (*Cassell's French Dict., 1st edition*).

Maiden soil.—W. D.—It matters not whether the soil be clay, sand, loam, or what else. If it has not been under tillage before, it is called maiden soil. So when land is taken for gardening purposes that has never been so used before, it is generally termed maiden soil, in the sense that the spade now enters it for the first time. To say that land has never been cultivated before is of course nonsense, no one can say that even of a bog. No one can say absolutely what is and what is not maiden soil.

Propagation of Heaths.—Ernest.—To propagate *Ericas* is a slow and rather tedious business, but there is nothing difficult about it. The most important point being the exercise of constant watchfulness and care. Procure some pots and bell-glasses to fit. Those made by Paskell, of West Kent Potteries, Chislehurst, are admirable, and the most convenient size is 12 inches diameter. Put in a third depth of drainage consisting of broken flower-pots. Over the drainage spread chopped sphagnum one inch deep, and then fill up to within two inches of the brim with a mixture of peat and silver sand equal parts, and lastly one inch (or more, even to the brim) of clear silver sand. The next thing is to carefully wet the soil all through, and the best way to do it is to stand the pots in water, which is far better than pouring water on them. The grand point of all is to take the cuttings at the right moment, and that is when the wood is about half-ripe, or in other words when it is beginning to turn brown. Of course this does not take place with every variety at the same season; therefore if you propagate heaths you must be always at it. Never mind; you may get good cuttings from almost every kind of heath in June, July, August, and September; and those are the months to be busy with them. Let the cuttings be from one to two inches long; the bark must not be bruised, the leaves nearest the base must be removed, and they must be inserted in the sand so that they will stand firm. As to distances, put them as close as possible. Take off the bell-glass occasionally and wipe it dry, and when water is needed dip them.

VENTILATION OF ROOMS.—Let us consider the condition of one of our sitting-rooms in winter. The fire burns brightly, and, as a consequence several thousand cubic feet of air, are hourly drawn up the chimney. Whence comes the air to replace this loss? The chinks in the door and windows are constantly admitting a stream of cold air, and thus ventilation is effected at the expense of draughts, which produce chilled feet, catarrhs, and so forth. Still, ventilation takes place. We are now supposing that the lamps have not been lighted; and we think everyone's experience will show that most rooms in which a fire burns well are tolerably well ventilated (*quoad* the amount of air) till, say, the gas is lit. The moment the chandelier comes into operation (supposing it to contain five ordinary fish-tail burners), the state of things is changed, and in the course of half-an-hour or so this change becomes distressingly perceptible. Why?—People never ask themselves this question. Because twenty-five additional pairs of lungs have begun to use up the air, each burner in use being equivalent to about five persons. This is the great defect of our modern dwellings. In olden times ventilation must have been far better than it is nowadays, when our demand for light is followed by so large a consumption of our breathing air. And why, again, is there this distinction between the fire and the gas? The fire uses up air, but it also acts on the *vacuum* principle, and produces a draught of fresh air in the room; but the gas does not. What, then, is the remedy? Convert the gas into a fire, provide it with a chimney to convey out the products of combustion, and compel it thus to ventilate the room as thoroughly as the fire does. Many methods of doing this have been suggested, but the one which has been found most satisfactory in operation, and of which we ourselves can speak in high terms of praise, is that which is known as the Ventilating Globe Light. Here, again, arises the question, Can ventilation be effected more easily in a small room than in a large one? This is a problem of some gravity; and, in our opinion, its only correct solution is that given by a mathematician, Professor Donkin, F.R.S. On this point we differ from both Dr. Smith and Professor Parkes. The former would, of course, allege that the smaller space is more convenient. The latter contends that a larger apartment is more easily ventilated. According as we view the matter from different stand-points, each is right, though both, in our opinion, are in some respects in error. In a small room, with a very powerful out-draught, the quantity of air demanded per minute might be smaller than that demanded for a larger one. Again, in a large room we have the advantage of a large supply of air to dilute the poisonous gas. A little reflection, however, will show that in both cases, unless the increasing impurity be kept under, the rooms will, at a certain period, become uninhabitable. This, we think, is a point which has been overlooked by Dr. Parkes. Those who read Professor Donkin's observations on the subject can decide whether we are right or not; but we confess that we cannot see what the size of the room has to do with the quantity of air to be supplied per hour. It is a matter for arithmetical calculation, but it seems to us by no means difficult to show that whether the room be large or small (assuming it to be constantly in use) the quantity of air introduced must be the same in order to reduce its atmosphere to the standard demanded by hygiene.—DR. LAWSON, in *Popular Science Review*, October.

The Gardener's Magazine.

SATURDAY, DECEMBER 14, 1867.

THE FRUIT AND VEGETABLE MARKETS OF LONDON are things of which no one can be proud. The enormous trade in these articles is perpetually burlesqued by the wretched character of the places in which it is carried on, and it is almost a marvel that the trade is carried on at all, or that a single inhabitant of the metropolis can ever be sure of purchasing a potato. What is Covent Garden market but a miserable sham? It is, in fact, not a market, but a rough rendezvous. At Spitalfields we are reminded of the times when there were market gardens a stone's-throw distance from Hoxton; for since that time the market has scarcely changed, except perhaps to become dirtier and darker, and more and more busy. Farringdon market would be a credit to the city were it covered in, and its northern side were galvanized into life; but it is anything but what it might and should be. At the Borough market a great trade is carried on, but the place is inconveniently situated, and is in no respect a credit to the district which is principally benefited by it. As for Bloomsbury, Clare, and Fitzroy markets, we need not mention them, for they exist more in name than in fact, and are not much better (in some respects worse) than the extemporized markets of the industrious costers, whom the police still graciously permit to occupy sundry bits of roadside waste in various parts of the metropolis. Take the four principal markets in which vegetables and fruits are sold, consider the extent and purchasing power of the metropolis, and say, have we any reason to be proud of these markets,—these dog-holes for chaffering, these make-believe shelters for honest people who come together to sell and to buy? Those who have travelled can best answer the question. Some amongst our readers have seen in provincial towns of small extent spacious, cleanly, well-ordered markets, with lofty roofs of glass to screen the people and their goods from the weather, and with beautiful exteriors that constitute important embellishments of the towns and cities that have taken such good care of themselves in this respect. Who has ever been startled or enraptured with the façade of Covent Garden market? Indeed, we do not know if it has a façade, unless we may call the semi-frontage that looks towards Drury Lane by such a name.

The other three markets are still less ornamental, and in respect of outside show contribute in no degree to the adornment of the metropolis. But we might be careless of appearances were the traders and their wares cared for as they should be. The central avenue in Covent Garden is always stored with the most sumptuous fruits and flowers that the skill of man can produce in these climates; and there is a footway of about ten feet in width for pedestrians who desire to see them and make purchases. It is simply absurd. The real market is in the open air, and in such bitter weather as we have had lately carters, agents, porters, salesmen, buyers, have all been coughing together, and contracting for catarrh and consumption while bargaining about celery and potatoes. You shall see any day just now great batches of delicate stove and greenhouse plants set out on cold pavements, in a killing draught of wind, perishing at a much more rapid rate than they have been grown, and those that remain long unsold are soon past the possibility of being sold, for the cold kills them and there's an end. We have seen dozens of poinsettias lately melted down by frost into tufts of woolly-looking rags; and if these are beneath notice as furnishing an argument for a better market, it may not be amiss to reflect upon the bodily sufferings of persons whose avocations compel them to frequent the market, and endure exposure to the weather at all times and seasons. The rental of Covent Garden market is sufficient to insure for the whole of the trade carried on there decent shelter and convenience; and if the frequenters of the market were to combine their forces, they might effect a great saving to themselves by constructing elsewhere a market of their own, in which to follow their business in some degree of comfort.

It is with great pleasure we hear that the Society of Arts has directed its attention to this important subject, and, on the recommendation of the Food Committee, has begun to collect information with a view to promote the establishment of

additional markets. On every occasion that we have made remarks upon the metropolitan markets, we have pointed out the necessity that exists for a few suburban markets, to serve as centres of trade for the principal districts at a distance of from two to three miles from the heart of the City. It would be far better to divide than to concentrate the trade. London has become too vast for any central spot to be of service to the whole, and Covent Garden may well be left to serve for a reduced trade, rather than for any enlargement to take place now that half a dozen districts are in need of markets of their own. We would point to such spots as Dalston Junction and Camden Station on the north; Stepney Green on the east; Kensington Station on the west; and the Bricklayer's Arms Station on the south of London, as representing very nearly the centres of populous localities in need of markets. Now that the City of London is pushing forward the splendid new meat market on the site of Old Smithfield, and is about to construct another new market expressly for the sale of foreign cattle, it is time the producers of market fruits and vegetables made a stir in their own behalf for increased and improved market accommodation. How it is that they endure such rough usage as they are subjected to, is one of the mysteries of the nineteenth century.

Mrs. PINCE'S BLACK MUSCAT GRAPE has more than justified the high praises that have been bestowed upon it. We have received, a few weeks back, from Messrs. Pince and Lucombe, of the Exeter Nurseries, a handsome bunch which was cut before the colouring process was completed. The berries, though unfinished as respects colour, have a superb flavour, highly charged with the peculiar muscat tone for which especially this grape is valued. We are informed by Messrs. Pince and Lucombe that they have been compelled to cut all the fruit earlier than they wished to do in consequence of the complete exhaustion of their stock of young canes, and the necessity, therefore, of immediately propagating for the next season's supply.

CONTINENTAL HONOURS.—We shall endeavour shortly to enumerate all the winners, amongst English exhibitors, of prizes at the Paris Exhibition. For the present, we can only announce that Messrs. Veitch and Son have gained one of the large gold medals; Messrs. Sutton and Sons, a silver medal; Messrs. Downie, Laird, and Laing, a bronze medal for pansies; Messrs. Shanks and Son, the only medal awarded for lawn mowers.

NEW PARK AT PORTSMOUTH.—The *City Press* mentions that, through the liberality of the Queen, an area (which is Crown property) of about fifty acres of meadow land, dotted with fine elm-trees, at Portsmouth, is to be given over to the people, who will now have a Victoria Park, "on payment," as the Treasury missive has it, "of a rent consistent with precedent in similar cases."

UTILIZATION OF LONDON SEWAGE.—Mr. J. C. Morton has informed the *Times* that the preliminary experiments with sewage applied to the Maplin Sands have quite fulfilled all reasonable expectations. He is satisfied—and few men are better qualified to pronounce an opinion on such matters—that the sewage will enable very large crops of Italian rye-grass to be taken off Maplin Sands, and already the application of sewage to poor light sandy and gravelly soil has resulted in excellent crops of corn, roots, and rye-grass. Mr. Morton's experience is highly encouraging, as it gives some reasonable hope that the Essex sandy wastes will by-and-by supply milk and meat to London in abundance, as a return for that which threatened to convert the Thames into a pestilential sewer. This is good news, far better than even of a battle gained in a just cause, and full of promise of ameliorating the physical evil with which we are called upon to keep up so stern a struggle.

AN INK FOR GLASS.—M. Kessler, of France, has, by means of hydro-fluoride of ammonia and hydrochloric acid, properly thickened, made an ink by which, with any pen, ineffaceable characters can be traced on glass. This ink will be of service to the chemist and apothecary in labelling bottles and marking gradations on glass, and no doubt will also be of great service in museums, and possibly in gardens also.

ABYSSINIAN EXPEDITION.—We learn from *The Lancet* that considerable quantities of lime-juice will be forwarded to Abyssinia for the use of the troops, and that, on the recommendation of a medical officer of the Guards, a supply of the extract of wild lettuce will also be sent. This drug is a valuable sedative and anodyne, which has less effect on the nervous system than opium. It is prepared from the milky juice of *Lactuca virosa* chiefly, but sometimes also from *L. elongata* and *L. scariosa*, all of which are more powerfully narcotic than *L. sativa* and its garden varieties.

LONDON CEMETERIES.—Twenty-one cemeteries within the metropolitan district supply 577 acres appropriated to the burial of the dead. There have been already about half a million interments in these cemeteries, and at least 40,000 burials are added to them every year. Some of the cemeteries are getting much fuller than others. In the 33 acres provided by the City of London and Tower Hamlets Cemetery Company 113,173 burials had taken place at the close of the year 1865; the interments there are at the rate of about 10,000 a year—one-seventh of the whole number of the deaths in the metropolis in a year. In the Abney-park Cemetery of 33 acres there had been 38,639 burials at the end of 1866; and in the 27 acres of the St. Marylebone Cemetery, at East-end, Finchley, only opened in 1865, there had been, in the middle of the present year, 28,092 interments. In another cemetery at Finchley, belonging to St. Mary's, Isling-

ton, burials are proceeding at the rate of 100 per acre every year. The drainage of the metropolitan cemeteries is generally into the public sewer, but not always. There are instances of drainage into an open stream, a brook, the Wandale, the Brent, the Thames. In St. Marylebone cemetery, Finchley, drain-pipes are laid at the bottom of every grave, discharging into a ditch which runs into a small stream; but little or no water passes out of the cemetery, in consequence of nearly every grave having planted on it a tree or shrub. Graves reopened show roots of trees more than 16 feet deep. Several kinds of willow and poplar trees planted on graves have this year made from four feet to six feet of wood.

A DISPUTED JUDGMENT.—As judges at horticultural shows are known not to be immaculate (and usually do not profess to be), and questions are frequently raised about the validity and legality of their decisions, the following report of an action tried at the Manchester County Court, on the 8th of November last, may prove interesting to many of our readers. It is true this action related to a judgment at an agricultural show; nevertheless, it illustrates the law and equity of judging in general, and ought not to pass into forgetfulness. This action was brought by Mr. Howarth Ashton, of Prestwich, against the Worsley and Swinton Agricultural Society, to recover £3, the amount of a prize offered by the society, at its show in August, for the best cob mare or gelding not exceeding 14 hands 2 inches in height. Mr. R. B. B. Cobbett appeared for the plaintiff, and Mr. Edwards for the defendant. The judges at the show in question awarded the first prize of £3 to the plaintiff; but on a protest subsequently being made by another exhibitor that the mare was above the prescribed height, the matter was referred to Mr. Greaves, of Altrincham, who was described in the prize list as the "veterinary referee." The mare was measured by him, and found to be 14 hands 2½ inches in height, but the plaintiff then required that the animal's shoes might be taken off, and this being done, its height appeared to be 14 hands 1½ inches. Mr. Greaves decided against Mr. Ashton, but the plaintiff insisted that he was entitled to the prize, and hence this action. The real questions which were submitted to the Judge (Mr. Owens) were: 1, Whether the mare came within the class in which she was shown; 2, whether, if she was above 14 hands 2 inches with the shoes on, the plaintiff was justified in requiring that the measurement should be taken with the shoes off, or, in other words, whether the height of a horse was to be taken with or without its shoes; and 3, whether the decision of the veterinary referee was binding on all parties under the rules of the society. After hearing the evidence on both sides, the Judge said that, as to whether the mare came within the class, he decided in the affirmative; because, in the same way as the height of a man was to be taken without his shoes, so the height of a horse, on such words as the society's rules contained, was to be taken without its shoes. If it had been proved to him that the contrary was the regular custom, that would have altered his decision. The other question was whether Mr. Greaves having decided that it did not come within the class was to be conclusive against the plaintiff; and it had not been proved satisfactorily that Mr. Greaves was to give a final and binding decision upon a matter of this kind. It was stated in the prize list that he was the veterinary referee, but it was difficult to ascertain what the real meaning of that was. There was another question, whether, supposing the referee's decision was to be final, the question of the height of the horse would come within his office; and it seemed that this was by no means clear. Mr. Ashton's mare had been decided by the judges to be the best animal; but it had been set up that the veterinary referee had given his decision the other way. He (the Judge) could not hold in favour of the latter contention, unless it had been clearly made known before the show that the veterinary referee was the man who gave the final decision, even after and independent of the judges; and this was a point which had not been proved before him. He therefore decided in favour of the plaintiff.

IPSWICH HORTICULTURAL SOCIETY.

The Annual General Meeting of this Society was held on Thursday, December 5th. The Chairman (Mr. A. Porter) opened the proceedings by reading an abstract of the receipts and expenditure of the past year, which were as follows:—

1867.		RECEIPTS.	£	s.	d.
To balance in hand last year	71	13	10
Subscriptions received	136	0	6
Cash taken for admission (1st show), May 24,	1	4	0
ditto ditto (2nd show), July 4,	51	10	3
ditto ditto (3rd show), Sept. 5,	14	17	0
Cash received for letting marquees	14	17	0
Ditto received for letting refreshment stalls	4	0	0
Interest received for money invested	3	6	0
Donation from East Suffolk Militia Band	1	0	0
Ditto from 1st Suffolk Rifles' Band	1	0	0
			£299	13	7
1867.		EXPENDITURE.	£	s.	d.
Paid in prizes	108	14	6
Remuneration to Judges	10	8	0
Expense of bands	44	6	2
Advertising and printing	21	8	0
Hire of marquees	6	0	0
Hire of storeroom and committee room	4	12	0
Preparing and fitting up shows	29	10	11
Postage and stationery	1	11	7
New marquee for Secretary, and repairing marquees	10	6	9
Insurance of stock to Christmas, 1867	0	18	0
Hire of Arboretum (1st show)	1	10	0
Secretary's salary	10	10	0
Collector's commission on subscriptions	13	12	0
Ditto ditto upon letting marquees	0	18	9
Balance in hand	35	6	11
			£299	13	7

Mr. W. SMITH proposed, and Mr. OLIVER seconded, the adoption of the report, which was carried unanimously.

The CHAIRMAN said that the results of the year's operations had indicated that the greatest economy had been used, and, considering they had had a succession of inauspicious show-days, it was a subject for congratulation that

they had such a balance as £35 (hear, hear). The first show of the season was held in May, and although Nature usually smiled at that period, however, on this occasion the day was wet and boisterous, and the drenching rains prevented the society getting a good beginning for the year. Gardeners were not to be daunted by weather, and frequently lost a night's rest to secure the objects they sought; but when their show-days came in wet, they must all succumb to the consequences. The forthcoming year promised to be one of great importance, inasmuch as the Suffolk Agricultural Society's meeting was to be held in Ipswich. This show would bring a dense influx of visitors, as cattle would again be permitted to be exhibited; thus an opportunity would be given for the Horticultural Society to hold a show of a distinguished character. In order to do this, it would be necessary to enlarge their prize-list, so as to give such prizes as would attract the great horticulturists and floriculturists from a distance, and must practically constrain people to visit the show by the excellent character of their exhibition. But if they have a grand show of this description, the burden must not fall upon the society's finances, which were not sufficient for such an undertaking; but as their prize-list was (unavoidably) a meagre one, he would suggest that they seek assistance from outside. Considering the long standing of the society, its position, and the good which it had accomplished, he believed there would be no difficulty in getting a number of local gentlemen to put down their names as guarantors for the payment of any extra expense they might be put to in offering further important prizes, although they might not be called upon to pay anything; for, apart from the number of visitors to the town, there was the fact that the show would probably be continued for two days. It would be well also to invite eminent horticultural and floricultural exhibitors from a distance; but they would not be expected to come unless the prizes were sufficiently large. If they were favoured with fine weather, there was no doubt that the finances of the society would be improved considerably. If they did give a show concurrently with the Suffolk Agricultural Meeting, they were bound to make it one that visitors really could not resist seeing, and such as would satisfy their minds that they had done justice to themselves and to the public. The committee had never desponded, it was unpropitious weather only which had caused them to be left with so limited a balance.

The Vice-Presidents were re-elected, with the exception of the ex-mayor, who withdrew, but continued as a member.

Mr. PORTER proposed that Mr. W. Groom, an ardent horticulturist and floriculturist, should be appointed honorary secretary for the ensuing year.

Mr. OLIVER seconded the motion, which was carried with applause.

Mr. GROOM, in acknowledging the compliment, said he had to thank them for the honour in appointing him Honorary Secretary, trusting his humble assistance coupled with his limited experience in horticulture might prove beneficial in promoting the interests of the society. He regretted to find that the balance in hand was considerably less than it had been since he had known the society, but hoped next year to be able to congratulate them on being again one of the most flourishing societies in the kingdom. It is generally admitted that horticultural exhibitions contribute some benefit to most branches of commerce, more especially in an improving town like Ipswich, and trusted they might meet with more liberal support than they had done during the last few shows. There was one thing he should like to see better encouraged, that was Cottage Gardening. Nothing enlivened the appearance of the cottage more than a neatly kept garden, or a few clean and healthy window plants, the cultivation of which tended to promote happiness to the labourer, and improved him morally and physically. He should therefore feel much pleasure in offering prizes of 7s. 6d. and 5s. for the best collection of window-plants grown and exhibited by cottagers. This being favourably received, six other similar prizes were offered by the Secretary, Mr. LONG, and Messrs. REA and PACK.

A vote of thanks being moved to the Chairman, the proceedings terminated.

A NEW MODE OF PRODUCING ICE.—Ice has passed from the list of luxuries to that of necessities in all great towns, and an enormous traffic, carried on in large ships which go long voyages, supplies even the tropics with the crystallized winters of the North. But when ice cannot thus be obtained, a good way of making it is most valuable both for medicinal and domestic reasons. Of course, every chemist knows a dozen methods of freezing water. The fault of the ordinary recipes is that freezing powders can never produce more than a thin film or crust of ice. Recently, however, a most efficient and satisfactory process has been patented by Mr. Edward Welch, of Harrow—one of the many able students turned out by the engineering department of King's College. It consists of an air-pump with double action, communicating to a cylinder, with concentric chambers surrounding the receptacle of the water to be frozen. The water occupies the central space; next is a circular chamber, containing ether; then a third, filled with powdered charcoal; then a fourth, called the condensing chamber; and, finally, a coil of small tubing inside a larger pipe wound round the last space. The arrangement is of necessity hard to comprehend without a diagram, but the action is so simple that it will go far to explain the nature of this most ingenious machine. The pump, when set in motion, produces a vacuum in the ether chamber; the ether rises in vapour towards the pump through one of the union pipes, producing a great degree of cold; a compression pipe from the pump forces it back to the condensing chamber, and also through the small tubing around this; and while the compression reduces it again to the liquid form, a stream of water through the outer pipe of the condensing coil carries off the heat thus engendered. Meantime the partition of powdered charcoal most effectually cuts off all possible communication of the disengaged heat to the ether chamber or the water which is to be frozen. There is a receptacle fitted with a float-valve which takes the ether, now reliquified, and discharges it back again into the vacuum chamber, so that, once set in motion, not a particle of the costly spirit escapes from the machine. It rises in vapour, freezing the water; is compressed back again; reliquified; its caloric abstracted; that caloric taken away altogether by the outflow of water; and the transformed vapour then restored to its original duty, with an unbroken and most unfulfilling succession. The principle is perfect, and the practice so good that in about a quarter of an hour a cylinder of solid ice is produced; nor is there any limit to the manufacture except labour; for the ether never diminishes. The inventor proposes to simplify his pump and work it by an ordinary head of water, when the kitchen tap of a dwelling-house would accomplish every step of the process except lifting the ice out and putting it on table. As a method of supplying real block ice—especially for hospitals, foreign stations, and out-of-the-way places—the machine is as useful an application of high scientific knowledge as could be seen.—*Daily Telegraph.*

SOME PLANTS AND FLOWERS FOR CHRISTMAS DECORATIONS.

There is no lack of subjects which can be brought into use at this festive season, if we take the trouble to examine the lists of flowering plants and berry-bearing shrubs. Some amount of convenience and skill and patience to grow them are, of course, required, but nevertheless it is matter for regret that we seldom see these seasonable plants and flowers grown in sufficient quantities to make a display of any importance. Many of the plants which I shall name in the course of these remarks are well known and justly admired for the ordinary purpose of decoration, but still I have seen but few attempts to grow them specially for the purpose for which they are so admirably adapted at this Christmas time. I therefore propose to name the best of the plants and flowers which can be had at this season of the year, stating some of the uses to which they are adapted, with some account of their cultivation.

I shall place first on the list the berry-bearing *Solanums*, such as *S. capsicastrum* and *S. pseudocapsicum*. These may be said to be everybody's flowers, as they are as easy to grow as geraniums. The only cultivation they require is to pick off all the berries in the spring, and then harden them off prior to being planted out in a rich moist piece of ground towards the end of May. After this water occasionally in dry weather, and keep them free from weeds. Towards the end of the next September carefully lift them, and pot them in as small pots as possible, using sandy soil; then place them in a cold frame or pit for a fortnight, keeping them rather close and shaded during bright sunshine. Afterwards remove them to an airy shelf in the greenhouse, where they may remain for the winter. The result of this treatment should be plants in full vigour and loaded with bright large berries at Christmas. The purposes for which they can be used in the way of decorations are various. A well-grown nicely-furnished plant makes an admirable subject for dinner-table decoration, and cheerfulness may be promoted by placing a few plants in conspicuous positions about the house, and especially in the reception rooms. If a plant or two can be spared, they cut up admirably for filling flower-stands and vases. I once saw a few sprigs used in filling a vase, in conjunction with some fronds of ferns; the effect was very pleasing. But, to my mind, the *Solanums* are never more effective than when grown as standards about two feet high. To do this, training must commence with a young plant, and all the side-shoots be nipped off from time to time. About the third year they begin to form nice round heads. As they get age they make very telling objects, as the habit is much more graceful than when grown as bushy plants. Many complain of the frequent attacks of green-fly upon these plants. This is generally the result of a starved condition of the plants, and an insufficiency of fresh air.

The next subject I shall deal with is the *Poinsettia pulcherrima*. This is, without doubt, the greatest gem of the season, for, besides being a beautiful plant for the dinner-table in its entirety, it is also a lovely subject for cutting up for the filling of vases, &c. The most beautiful effect that ever I saw made with this plant was by a lady of rare taste in these matters. It was in this way: two pans of close-growing *Lycopodiums*, about twenty inches over, were selected from the fernery. They were well furnished, as no part of the pan was visible. In the centre of each pan was placed a *Roman Narcissus* in full flower. This was encircled by a broad band of the *Poinsettias* from cut flowers, the centre being the highest, and the following rows decreasing in height towards the outside; and round the edge of the pan was placed a ring of the *Helleborus niger*, or Christmas rose, fully expanded. The effect was rich and beautiful in the extreme; the contrast between the flowers and the mass of green beneath them was very striking. The narcissus was the only subject which interfered in any way with the *Lycopodium*, as that was inserted with its bulb and roots attached. But the others were used as cut flowers, and were easily fixed in the soil of the pan without interfering seriously with its occupants. The *Narcissus* and *Helleborus* were the first to require renewing; the *Poinsettia* kept fresh and beautiful for more than a fortnight; the only attention it required was to have just the base of each spike cut off every other day, to allow them to imbibe moisture more freely, and again inserted in the soil, giving only as much water as was required to keep the *Lycopodium* alive.

The *Lycopodiums* of course suffered considerably from the constant interference attending the changing of the subjects, as well as from the dry air of the room. But they soon recovered when transferred to their old quarters. The position of the pans when dressed was on each side of a camellia in full flower, upon a sideboard in the front hall, which was heated by a coil of hot-water pipes. I must leave the reader to guess what the effect was; my own conviction is, that I never under any circumstances have seen the *Poinsettia* used so effectively as

in this instance, impossible as it is to place them where they would not please even an indifferent observer. I have given the above manner of using them for indoor decorations because it is likely it may be the means of suggesting to the minds of some of our fair readers, if not exactly the same, some similar means of using them for their own homes. A similar effect might be made without the *Lycopodium*, by using wet silver sand and some nice green moss from the woods or banks instead; and in the place of the *Helleborus* and *Narcissus*, white tulips may be had: many have such varieties as Queen Victoria forced for Christmas. The *Poinsettias* may be also grouped in pots, or placed singly in any conspicuous warm place about the house, for whosoever they can be seen they are sure to win admiration. They are properly stove plants; they therefore require warmth, and to be excluded from cold draughts. I shall not detain the reader with any cultural remarks, as our respected coadjutor, Mr. McElroy, lately gave full details on the subject.

Perhaps the most telling object for pot culture, and which our Editor does so well, of the berry-bearing shrubs is the *Crataegus pyracantha*; but few people take the trouble to do it well in pots. It is nevertheless a fine subject for Christmas decorations. Its beautiful coral-like berries are usually produced in such masses as makes it desirable to have this plant largely grown by those who wish to promote variety and good taste in indoor decorations.

Next to this should be placed the varieties of *Skimmias*, especially such sorts as *S. Reevesii* and *S. oblata*: these are nice-habited plants when well grown, and may be had with a goodly number of berries upon plants eight to ten inches high; but the larger the plant the better the effect. They are easily grown in a greenhouse temperature during winter. This does not exhaust the list of berry-bearing plants, for we have the pretty *Rivina humilis* with its bright red berries, as well as the *Aucuba Japonica*; and those well up in stove plants may also have *Ardisia crenulata*; while the shrubberies ought to furnish the common *Euonymus Europaeus*. For more seasonable flowers we have the *Chinese Primulas*, *Mignonette*, *Chrysanthemums*, *Winter-flowering Carnations*; as well as *Camellias*, *Cyclamens*, and those gems of gems, *Euphorbia Jacquiniflora* and *Thyrscanthus rutilans*.

C. C.

A WORD ABOUT 'CAMELLIAS.

I know very well there's nothing new to be said about camellias; everybody almost who can handle a pen has written about them. I hope nobody will expect anything new from me, for I go on in the old way, like a horse in a mill-track; and I've only got to say about the old way, that it's a very good way, and a way that pays me well enough to grow camellias,—that I shall not soon be tempted to experiments. Why write, then? you will ask. Well, I have been pressed hard to tell some certain folks how I manage to fill my boxes with white camellias for the market, from the beginning of October until the end of February, from a very small house and a very few plants. Well, these folks want to know, and I'll tell them in a word. It's done by good management. My trees are all in tubs, and they are now so loaded with buds that they look as if a heavy shower of buds had fallen upon them. I can truthfully say that they have no particular treatment; there is really no secret to tell, and I begin to wonder now what I have to write about. However, I have made a beginning, and I must make an end. Two years ago I shifted my trees out of starving pots into tubs, by what would be called a large shift. I wanted big trees and flowers by thousands; things you can cover with an umbrella are no use to me. The soil I used was good turfy loam only. When they were tubbed, I put a ring of clay on the soil round the stem of each tree, in order to restrict the watering to the old ball, and keep the new soil dry, or nearly so, for a time. By pouring the water within this circle of clay the actual roots were nourished, and the new soil was not made sour. By degrees the roots pushed into the new soil; I could tell how the roots were pushing by the growth of the shoots: the head of a tree will always tell you what the roots are doing. I kept the rings of clay on for at least a year, and then removed them, and watered the whole of the soil in the tubs. Now as to watering: in the first place, I never use pure water at all; in fact, haven't any. All the water in the nursery is tainted with sewer; in other words, it is weak liquid manure—very weak, but it always contains something for plants to feed upon. What stuff it is to talk of giving one dose of strong manure water and so many doses of pure water, as some writers who shall be nameless do! If once you begin with manure water, go on with it all the while your plants are growing or flowering, but have it so weak that it will not force the growth into rankness, or cause

the flowers to burst, or show impure colour; have it so weak that if you had to drink half a pint of it you would not throw up your heart directly afterwards, or swear that you were poisoned, and must call in the coroner. When watering is going on in the houses here there is a perceptible odour afloat; that to me is pleasant, for I know that inodorous manures are of little value. Now I don't mean to say that wherever camellias are grown the house should be rendered unsavoury to the nose at every watering of the plants. It is not for me to say what ought to be in any case; I am just complying with the request made, that I would say something about my camellias, and in respect of watering I have said my say.

Well, now about thinning and buds falling. I cannot afford to thin; I cannot afford to let a bud fall. Every flower is worth to me—so much; I am not seeking trade, and shall not name a price. I say I never thin. No; for me to do so would be absurd, and for anybody to do so is in my opinion a rather unwise proceeding. But the trees make more buds than they can open, you say. Nonsense; it is your business to play the part of doctor, and assist at the birth of all these flowers, not destroying any. I dare say the perpetual supply of extremely weak manure water has something to do with the enormous production of flowers which render my camellias the most profitable things I grow. People say, don't part with the secrets of your trade. Bah! am I to set my trade against the march of knowledge, and meanly keep to myself what may benefit thousands? No. I say, then, I never thin the buds, and never have any fall; but, mind you, I must have trees in perfect health if all the buds are to be allowed to open. In my camellia house now there is a small tree that I bought a year ago in a rather poor state of health. Give me another year with it, and health shall shine upon its dark green leaves, but for the present I must not allow it to open out all its buds; in fact, I did thin this one two months ago. I shall be content with about two hundred flowers from it, but I must have five hundred next year, and the year following a few more.

The falling of the buds. Ah! a few evenings ago I was turning over the pages of the Magazine, and I lighted on an article from the pen of our Editor, in which he gives a category of causes of buds falling, and a small cyclopædia of remedies. Read that article, all growers of camellias, and it may do you good. You will find it in the number for Dec. 15th, 1862; it is profound in its analysis of physiology and astonishingly practical in pointing out remedies for ills the camellia is heir to. I can't do anything like that. I can only say in my rough way that good management is the secret of success, and I suppose every body knows as much as that. But, I will tell you that with a large and increasing business, with many cares and labours, I make it a rule to look after the camellias myself. What heat, think you, are we keeping them at now to fill our boxes with flowers for the market twice a week? Well, just enough heat to keep out frost and no more. Perhaps if I pushed up the heat smartly the buds might come down like a shower of rain; they look at present as if a shower of buds had fallen and just stopped where they are. Well, we shall not, I dare say, push up the heat, but be content to take it easy and have a long supply of flowers, and get every bud open in due time.

I know how it is that horticultural writers are compelled to harp ever on this much-worn string. People put their camellias out of doors in a well-selected spot, and forget them. The roots get dry, the bark gets hard—for, you know, that must happen with dry roots—but the plants, being capable of bearing bad treatment, still live and look very well. By and by they are housed, and being dry at the root they get an extra dose of water. For a time the water runs away next the sides of the pot and does no good; but oft-repeated doses tell at last, and the roots get moistened through. Thereupon there is a general swelling of all the joints and a softening of the bark, and in this process the buds are pushed off. I knew a case just like it in the human subject. A lady had a splendid head of hair—wonderful hair; equal no doubt to the tresses of Lady Godiva. She had an attack of dropsy, and was for a time much swollen. She was cured, but as she got well all her lovely hair came off. When I heard of it, I thought how like it was to the falling of camellia buds; there was a change in the mechanical texture of the skin, and what would hold in the first case would not hold in the second. To be sure, the order of phenomena producing analogous results was opposite: in the plant there was first a shrinking, in the lady there was first a swelling, but in both cases the foundations were loosened, and the fall was the consequence. I hope I am understood. I am not used to this sort of thing, and am glad here to make an end of it.

ROBERT OUBRIDGE.

Church Road Nursery, Stoke Newington.

GLADIOLI FOR CLUMPING.

From time to time it has been our endeavour to simplify the cultivation of this glorious plant, and it is to be hoped that our readers have derived some benefit from our endeavours. The subject acquired peculiar interest a few years ago by the sudden expansion of the Gladiolus in the sunshine of popularity, and the almost simultaneous outbreak of what was called at the time the "Gladiolus disease." Truly, this flower well deserved to be a favourite, and to have a place in every garden. One of our most important tasks has been to show that this bulb may be grown in common soils, and may be assisted with common manures. Once upon a time, it was loudly proclaimed that manure of any kind would be death to it. No doubt some cultivators poisoned their bulbs by over-doing them with strong manures; but carefully conducted experiments prove that it will benefit by moderate manuring to the same extent as the crocus. Experiments have also proved that peat is wholly unnecessary, though in peat districts the bulb may be grown to perfection, and that any ordinarily good garden soil is sufficient for all its wants, if aided by judicious and quite moderate manuring. The Gladiolus is a plant for everybody, and therefore needs not any peculiar treatment; in fact, the simpler and more commonplace the treatment the better. Let me give you an example. In the early part of the year, I had potted all the stock of our home-grown bulbs I told you of last year. They were rather retarded than encouraged in growth, and were really very backward in the early part of May, when I had them planted out from pots into the open borders. The "grass" was not more than three inches high in any case at that time, therefore they literally had to "make themselves" in the borders. Now those borders consist of a stiff loam, deeply and frequently dug, and abundantly manured. In no case was it possible to put a clump of bulbs over a bed of recent manure, and therefore there was no reason to fear disease; but the soil was (and is) rich with annual dressings of hotbed dung, and these borders form the front lines of the rose quarters, and are treated just as if to be planted with roses. I remember giving instructions that they were to be turned out of their pots without the disturbance of a single crock, and that this was done faithfully I had proof enough on the 26th of November last, when I took them all up myself, and found the crocks underlying the bulbs, and the bulbs in the most perfect condition of ripeness.

It is quite certain that it is not advisable to leave these bulbs in the ground all the winter, though it may be done at a risk, and turn out well. Nor is it advisable to leave them in the ground later than about the middle of November, because, although the leaves may still be green, the bulbs will be perfect by that time (if ever), and in the event of mild weather in December they are pretty sure to begin growing again, to their injury. I have known the new crop of bulbs, instead of resting and ripening, to begin growing as soon as formed in the autumn, and afterwards to be caught by severe frost and completely destroyed; whereas, had they been taken up, the second growth, and the subsequent destruction, would have been both avoided. Those, like many other corms (for bulbs they are not, though that matters but little), will bear both damp and cold better if perfectly dormant than when growing; but the wise man will not expose them to either of those influences, but will house them in good time, and take proper care of them afterwards.

All our Gladioli for 1867 were potted in the first instance. The potting took place in January and February, most of them being potted in 48-size, three bulbs in a pot, in a rich light mixture, in which there was not a particle of peat, but chiefly mellow turfy loam and thoroughly decayed hotbed manure. After potting, they had no better quarters than common cold pits and frames, and when turned out three potsful of bulbs were employed for each clump, making an average of nine bulbs to a group; and, as remarked above, they were turned out with such care that not a root was disturbed. The bloom in the past season was glorious and long-lasting, for, on the 26th of November, when I lifted them myself, there were many spikes of flowers, not yet expanded, that would have opened had the bulbs bearing them been potted and housed. But the whole stock was treated in the rough and ready manner; they were grouped in sorts with all their leaves attached, and were laid in bunches on the floor of a greenhouse to finish off slowly; and they lie there still, as fine a lot of brown, hard, perfect bulbs as I ever expect to see in the trade. The usual rate of increase here is 100 per cent., that is to say, for every one hundred bulbs planted we look for two hundred the next season. The varieties differ very much in respect of productiveness; some scarcely give twenty bulbs for fifteen planted, unless cut expressly to compel them to increase; but the useful sorts that are planted in quantity, such as M. Blouet and Bronchloyensis, increase at a good

steady pace, and usually double their number every year in fine market bulbs, and give a lot of spawn besides, which the wise man will turn to account and obtain flowers from the next season. On many of the bulbs now lying on the floor of the house there are broods of spawn; or, in other words, clusters of minute bulbs of the size of peas, amounting to as many as thirty or forty, all of which may be expected to yield flowers late next season, and afford saleable bulbs next winter. If properly managed, therefore, the *Gladiolus* will pay English growers, and really deserves all the attention that can be reasonably given it, both by trade and private cultivators.

There can be no doubt at all now that the "*Gladiolus* disease" was the result of injudicious treatment. The flower acquired popularity rather suddenly, there was a "rush" to secure stocks of the best varieties and to increase them rapidly, and excessive manuring induced a morbid state of the plant, that continued through two or three generations, and was at last purged away by the cry that manure was poison to it. Starvation is oftentimes a curative proceeding, but it is an evil to be avoided, for individual strength and abundant progeny are to be expected only of organisms that are well nourished. But now that the disease is gone, and we have acquired numerous experiences, we may manage to hit the happy medium between too rich and too poor a diet; and I am quite satisfied that if we lay down a bed of half-rotten dung nine to twelve inches below the surface, for the roots of the *Gladiolus* to riot in, we shall poison the stock, and rue the day of our extravagance. But any good, sweet, friable soil will grow this plant to perfection; it will adapt itself to as many soils almost as a cabbage, certainly does well in peat, and any good loam that is enriched with quite rotten manure and leaf-mould, and in all good sandy soils of a nourishing nature, it flowers finely and multiplies freely. I am quite sure that mixtures of peat and loam are less to be desired than turfy loam without peat, but with a fair proportion of powdery manure and leaf-mould to enrich and mellow it.

Three years ago I speculated on a set of gladioli for the plunging system. The most showy and distinct varieties in the several sections were chosen, and we obtained picked bulbs of the sorts selected through Messrs. Barr and Sugden. Nothing could be more satisfactory than their behaviour. They were potted in what might be called fuchsia compost, consisting of about equal parts of turfy yellow loam and three-year-old hotbed dung, with some sharp grit added. But the frequent watering they required, the space of reserve ground they occupied, and the comparatively meagre show they made when in bloom, determined me to strike the gladiolus out of the list of plants most to be desired for this system. The two very showy sorts just now named are undoubtedly the best for any who are determined to grow them for plunging; and certainly a bed of *Brenchleyensis* presents a very beautiful appearance when well done. But the bloom is too soon over for the cost of getting up a display of pot plants, and there are so many other good things available at the same season, that the verdict must go forth that for the plunging system the gladiolus is not well adapted. But for bedding out and for clumps in mixed borders it is grand and so distinct in style of growth and range of colours, that every amateur should make a pet of it. For the front lines of a rosarium, for admixture with phloxes, pentstemons, cannas, and lilies, it is unequalled, and as a bedding plant, without the aid of other subjects, it is well worthy of the renown to which it has attained. But there is a certain leanness about it as a pot plant that should "give us pause" when we contemplate employing it in quantity for any special purpose, and particularly where plunging is practised.

These several points disposed of, we may approach the subject of cultivation in a more general and perhaps more useful manner. I will suppose that the manager of a large place desires to have a long-continued supply of flower spikes, whether for cutting or for keeping up the beauty and interest of the garden. His best plan will be to have his beds well broken up and liberally manured with leaf-mould and dung, taking care not to have the manure in a rank state, or in excessive quantities. He should pot his first batch in January, and keep them dry and cool, but safe from frost, until the leaves are an inch long, and then give them small doses of water, and so promote a slow healthy growth until the end of March or middle of April (as latitude and season may determine), when they may be planted out. A second batch should be potted in February, and be treated in the same way. In March a lot of bulbs should be planted out, and thereafter every month, until the middle or even the end of July, bulbs should be planted. The result will be an abundance of flowers from the end of June till some time far into the next year! Yes, all through the Christmas-tide gladioli

may be cut in plenty, and I make the market growers a free gift of this hint, and what follows as to the way to carry it out. "Carry it out!" Well, it is as simple a matter as the flowering of *Schizostylis coccinea*, which it is said nobody can do, just because nobody knows how, but the way to do which, in common with late-flowering gladioli, may be told in a word. In November lift all the gladioli that present undeveloped flower spikes; pot them with care, putting as many into a pot as can be crammed in without injury to the roots, and never mind if in the operation the mould is shaken off some of them entirely. Take care of the roots—that is to say, the actual feeding fibres. As to the bulbs, they will be as yet but half grown, and the check will influence them but little. When potted put them into snug quarters, but not in a hot place; a light airy greenhouse, where there is a little heat whenever the thermometer goes below freezing, is the place for them, but a peach-house or vinery will do very well, as they need no help from heat, if really safe from frost, to open out all their flowers. Consider how very much our home displays of chrysanthemums would be improved by intermixing these splendid flowers with them, and how conservatories everywhere, and even flower markets, would be benefited by this system of flowering gladioli in the depth of winter. This is just the way to do the *Schizostylis*. Plant it out in a rich, mellow, sandy loam, and let it remain out one winter. The next season the plant will form a large stool. Leave it alone until the end of October or middle of November, and then lift it carefully and pot it, and place it in any light cool house, and all its fine scarlet flowers will open perfectly. As a rule, the flowers of this plant are lost because just as they are opening there comes a killing frost, and they fall over like rags and are lost for the season.

It is commonly supposed that the "spawn" of the gladiolus requires one full season's growth before being capable of flowering; this is a mistake. I have just detached from one bulb of *Brenchleyensis* twenty-two little things of the size of peas, every one of which, I will engage, shall flower next season. If you observe the growth of this bulb, the flowering of the spawn is quite understandable; for at the very first start of the leaves into growth a new bulb (I mean corm of course, but the other word is more generally understood) forms on the summit of the one planted, and the flowers actually issue from the new, and not from the old, bulb. Hence it is that the sizes of the bulbs is a matter of very small importance. *The condition of ripeness* is what we should most look to in purchasing, to have them nicely finished, quite hard, and with not a sign of second growth about them. I remember that in 1866 we left a lot out of doors in pots till nearly Christmas, and then shook them out, and the pots were full of new roots. These were rubbed off the bulbs, and they were stored as usual, but several out of that particular lot died this year, whereas of our well-ripened and properly-harvested bulbs we scarcely lose one per cent. In planting, it is I think very objectionable to mix the spawn and the full-grown bulbs in the same bed, for an uneven growth and patchy bloom is the result. Plant them separately, and you will have uniformity, and the small stuff will flower later than the large bulbs, and so help to prolong the season.

The best of all the kinds for clumping is *Brenchleyensis*. It is the most rich and decisive in colour; it is the least particular about the quality of the soil; it is very uniform in growth, so that a bed of it shows fewest blanks and breaks of any, and it has the great advantage of opening nearly all its flowers at one time, thus presenting a full rich spike of its brilliant vermilion-coloured flowers. There has been much said about *Monsieur Blouet* of late, and it is certainly a fine variety, but *Brenchleyensis* beats it in effect, and is to be preferred where colour is a matter of prime importance. The last-named is really a rosy carmine, not scarlet, as usually described in the catalogues; and, as compared with *Brenchleyensis*, is the weaker of the two, and has not the merit of opening all its flowers at one time, so that when the spike is at its best there are always two or three dead flowers at the base to mar its beauty, unless removed. I find if I cut a lot of each of these, I must nip off the shabby flowers from *M. Blouet*, while there is no occasion to remove any from *Brenchleyensis*. At one pound per 100 *Brenchleyensis* is a cheap bedding plant, and at that price it can be purchased I am sure, for I bought a thousand a week since, and had some change out of a ten-pound note.

But scarlet flowers are not alone sufficient. There is a fine clumping variety called *John Bull*, which produces bold spikes of pure white flowers, which show superbly if bedded with some of the dark-leaved cannas. This may be obtained at about three pounds ten shillings per 100, or a trifle beyond that; and those who cannot afford to buy it by the hundred may do very well with a dozen at ten shillings, and wait for an increase. Another good one for clumps is *Fanny Rouget*, a

charming rosy flower, with shades of carmine to give it life without spoiling its softness of colour. This can be obtained at the same price as *Brenchleyensis*, though it is far less plentiful, its merits as a bedding plant being as yet but little known. As for *Monsieur Blouet*, which has been referred to so frequently, it is certainly a very desirable variety for bedding, the colours being rosy carmine in the early part of the season, but salmon-pink when it flowers late in cool weather. This is worth in the market more than *Brenchleyensis*, but ought to be obtainable at the same figure, for the simple reason that it is in some degree inferior.

After this selection there are hundreds that may be used for beds and clumps, but the following may be relied upon most surely where a rich and varied display is a matter of greater importance than any special excellence of individual flowers:—

Achille.—Bright currant red with white stripes, the flower small but showy. This is an expensive sort, being worth about £1 per dozen. It does not increase fast, but, with a dozen to begin with, a few years would make a hundred of them, and in some seasons there is so much spawn produced that the increase is enormous.

Aglæ.—A fine large flower of a bright salmon-rose colour. It is worth £2 per 100, and at that rate is cheap.

Aristote.—A beautiful rosy flower with red and purple shades; about the same price as the last.

Canari.—Yellow with rosy stripes; worth ninepence each in quantity.

Don Juan.—Fiery red with yellow spots, extremely showy and fine, and one of the cheapest.

Fulgens aurea-picta.—A splendid fiery red and yellow variety, of dwarf habit; well adapted for the front of a bed of cannas. This is worth about double the price of *Brenchleyensis*.

Madame Coudet.—Rose shaded with carmine; a very fine spike. Rather cheap—say, 30s. to 40s. per 100.

Napoleon III.—A brilliant scarlet with regular white stripes; one of the best varieties in cultivation. It is at present dear—say, worth a shilling each in quantity.

Floribunda.—White with pink and purple shades; one of the cheapest, but not one of the best.

Penelope.—Pale flesh with yellow and crimson stains; rather dear.

Triomphe d'Enghien.—Carmine with yellow stains. First-rate and cheap, being obtainable at a small advance on the rate of *Brenchleyensis*.

To make a long list would be far easier than to make a short one. For downright bedding effects, I should never care for the hybrids of the *Ramosus* section; but for small groups the *Ramosus* breed are useful, and it is not generally known that they may be left in the ground for three or four years, like crocuses; and, consequently, are well adapted for large places where there are borders that must be in great part furnished with plants that will take care of themselves. So also they are well suited for the amateur who loves hardy plants, as they suit to mix with herbaceous flowers. As to intrinsic merit, I would as soon have a spike of *Ramosus Queen Victoria* in a vase on the table as a spike of any other variety in cultivation, for its pretty flowers, deep scarlet with sharp white stripes, are unique. For cutting this is one of the most useful things that can be planted. So, again, *Ramosus Ne Plus Ultra* and *Ramosus Rose* are charming; and all these are cheapest of the cheap, and will become cheaper yet, when people learn to treat them in the same way as crocuses.

To find *Gladioli* of the *Gandavensis* breed suitable for clumps is easy enough. What I have been looking for to-day are the cheap kinds, such as men who are not made of money may venture to buy without fear of being accused in the bankruptcy court of having wasted their substance in riotous gardening. But as there are uses for the more expensive kinds beyond the rather superficial consideration of colour, we shall have to look them over presently, and so next week we shall probably have this subject before us again. S. II.

ROOTS, ETC., AT THE ISLINGTON CATTLE SHOW.

There is a grand opportunity for something new in the horticultural or floricultural way in connexion with the annual Cattle Show of the Smithfield Club. There is so much gallery space, and it is generally pretty well occupied with implements and collections of roots and seeds. But we see the same thing, or nearly so, every year; and in the vast round of rural affairs it would seem that by seedsmen, florists, and others who stand for the defence and advancement of the rural arts, some new and attractive features might be devised to give a more decidedly horticultural aspect to the galleries. Mr. Alinutt, of Fleet Street, offers barometers, thermometers, surveying tapes, and horticultural and agricultural books, and in that way does some good—much good, we hope, for he sells fairly and his instruments are good. There are also many displays of articles that are useful in every household, and country life is pretty well represented in every department except just that one in which we are chiefly concerned. But, taking things as they are, we must express our complete satisfaction with the displays of roots and seeds on several stands of well known firms. It is astonishing how truly ornamental mere turnips and mangolds become when skilfully grouped in quantities, but the grasses are badly shown, and such things as everlasting, which the seedsmen should encourage, are not to be seen at all. On our way round, the first display we noticed was that by Messrs. Sutton and Sons, of Reading. Here were piles of fine roots, with names and weights attached. Of turnips, *Purple-top Mammoth*, a round solid bulb, of a dull greyish purple colour, grows quickly, and produces a great weight per acre; weights, 9lb. to 13½lb. Sutton's *Champion Swede*, a globular purple-topped bulb; weights, 10lb. to 15lb. *Pomeranian White*, a handsome round bulb, well adapted for early

feed; weights, 9lb. to 14lb. *Imperial Green Glohe*; this is a better turnip than the common *Green Glohe*, and one of the best to sow after an early harvested corn-crop; weights, 7lb. to 12lb. *Mottled Glohe*, or *Grey Stone*, the best of the stone turnips; colour, purple and green in streaks; weights, 10lb. to 16lb. *Lincolnshire Red Páragon*, a handsome reddish purple bulb, quite round; weights, 9lb. to 11lb. *Orange Jelly*, a good turnip for late sowing; a very pretty lot, grown by Colonel Lloyd Lindsay, M.P.; this is a good turnip for the table as well as for the cattle shed; it never attains a great size. *White Tankard*, and *Red Tankard*, of great size and perfect symmetry; these are white-fleshed turnips of great value for early feed. Of mangolds, *Long White* and *Long Red*, 20lb. to 25lb.; *Intermediates*, 14lb. to 20lb. A fine heap of *Purple* and *Green Kohl Rabi*, a most valuable feed root, both for weight of crop and its general immunity from insect plagues; weights, 9lb. to 15lb. *Robinson's Drumhead Cabbage*, the best cattle cabbage extant, was shown here on a gigantic scale; one head alone must have weighed about 60 or more pounds. *Hamilton's British Volunteer Cucumber* had a good place in the centre of the stand, and deserved it, being of great size without coarseness, and of most perfect shape. A long *Chinese Yam* also attracted some attention. There were also samples of the following varieties of potatoes:—*Birmingham Prize-taker*, *Early Handsworth*, *Red Regent*, *Early Oxford*, *Sutton's Racchorse*, a handsome useful-sized white *Kidney*; *Wellington*, a blotched potato; *True Fluke*, *Sutton's Berkshire Kidney*, *Early Shaw*, *Skerry Blue*, *Pink Rock Dalmahoy*, *York Regent*, *Courtenhall Seedling*, *Red Ashleaf*, *Myatt's Ashleaf*, *Taylor's Second Early*, a fine large angular tuber. Many other interesting subjects might be found here, but these are all we made note of.

The display next in order is that by Messrs. Carter and Co., of High Holborn. This is rather rough, but consists of useful subjects. Of turnips the principal are—*Bronze Swede*, a small green and purple bulb, especially valuable for its hardiness. *Champion Swede*, a large purple-top variety; a heavy cropper, and keeps well in store. *Hertfordshire Round*, a handsome compressed white bulb. *Lincolnshire Red Glohe*, very showy and fine. *Devonshire Greystone*, a sombre purple and green variety of the *Mottled Glohe* class. *Green-top Yellow* is a handsome quick-growing sort, which takes the same place in the south that the *Yellow Scotch* does in the north. Of mangolds the true *Velvetham* was shown well, and also the *Warden*, a round yellow mangold. The *Metropolis Sewage Company* exhibited on Messrs. Carter's stand samples of long red mangold, grown on their sewage system of cultivation; they were of great size, solid, smooth, and in every respect good. Amongst Potatoes here we noticed *Thornton's Seedling*, an irregular kidney, like *Dawe's Matchless*, and if as good as that without being so subject to disease, valuable. The *Ash-top Fluke* looks well and eats well; it was one of the best in this collection. The samples of *St. Osyth Beet* were admirable for size, shape, and smoothness. Messrs. G. Gibbs and Co., of 25, Down Street, Piccadilly, made a grand display of roots and seeds. At the time of our visit none of the samples were labelled, and we only noted the fact that, in tasteful disposition and variety, this was one of the best root shows in the place.

Messrs. Thomas Gibbs and Co., corner of Half-moon Street, Piccadilly, had a fine spread of roots and seeds, the samples admirably selected. Here were some fine turnips, grown on the late Prince Consort's Royal Shaw Farm, Windsor, and growing samples of the new feed-grass, *Bromus Schræderi*.

Messrs. Wheeler and Sons, of Gloucester, made an interesting display of roots, grasses, and seeds. Here we made note of the following varieties of Potatoes: *Gloucester Kidney*, one of the best for mealiness and flavour; not a heavy cropper. *Fryer's Fluke*, good. *Milky White*, one of the very best. *Oxford Kidney*, a very neat red variety; the skin pale tawny pink; the form quite regular. *Alstone Kidney*, a very scarce potato, often recommended in these pages, and said by some to have gone out of cultivation. *Dalmahoy*, a capital early round. Two seedlings of the *Fluke* promise well, especially the one marked No. 2.

THE VARIETIES OF BEET.

During several years past collections of beets have been grown at Stoke Newington, and records have been kept of their characters and relative values, with a view to the ultimate selection from them of a few that are most distinct and deserving of general cultivation. It is intended now to transcribe from the Records of the Experimental Garden such particulars as appear likely to be of interest to our readers. To facilitate reference to the notes which follow, we have arranged the varieties alphabetically, according to the names by which we recognise them, appending the names of the traders by whom the samples were supplied in those cases where records of their names have been made.

BAILEY'S FINE RED, the same as *Cattell's Purple Top*.

CARTER'S ST. OSYTH (Carter and Co.).—A rather unequal sample; several gaps in the rows. The growth is very robust; the leaves are triangular, much wrinkled, bronzy purple with a crimson tint. The roots are of medium size, somewhat angular, irregularly tapering; the flesh brilliant carmine purple. When cooked, tender and delicious. This is one of the best beets for colour and flavour, but it is scarcely handsome.

CATTELL'S DWARF RED (Carter and Co.).—Leaves long and narrow, and peculiarly erect, purple and blackish green. Root large, spindle-shaped, symmetrical, but occasionally forked. When cooked, coarse-textured, somewhat earthy, and showing objectionable rings of a paler colour in the centre. Quite second-rate.

CATTELL'S DWARF PURPLE TOP (Sutton and Sons).—There are several distinct stocks of beets under this name. The one now under notice is of neat compact growth; the leaves oblong, wrinkled, bronzy purple with a blackish tint. The roots are extremely neat, very long and tapering, 2 to 2½ inches in diameter near the crown; the colour of the flesh blackish purple. When cooked, tender and sweet, and presenting a fine appearance when dished with green saladings.

COMMON RED.—There are several rather distinct stocks of the common red beet, but their distinguishing peculiarities may all be merged in one general description. The leaves are large and spoon-shaped, deep bronzy purple colour, glistening and almost metallic in appearance; decidedly coarse. The roots are various in size and shape, but mostly large, 3 to 5 inches in diameter next the crown, more or less forked, tapering, and irregular; the flesh is a fine dark carmine colour, and when cooked is tender and well flavoured. Where it is desired to produce a large bulk of useful beet-root for culinary purposes, this variety will be found profitable and good, but for any but rough utilitarian uses it is quite unfit, being ugly, coarse, and too large for ordinary purposes.

DEWEY'S IMPROVED SHORT TOP (Stuart and Mein).—Remarkably uniform in growth, scarcely a difference observable amongst hundreds of plants; leaves in a symmetrical tuft, oblong and smaller than the average, dark purplish red. Roots of the largest size allowable for a beet, yet by no means coarse; in form regularly tapering from the crown, very smooth and uniform; flesh bright crimson. When cooked, tender and sweet. This is one of the best beets in cultivation, though it is a shade lighter in colour than some may consider desirable.

JOSLING'S SCARLET is the same as *Cattell's Dwarf Red*.

LINDSEY'S SUPERB RED (Stuart and Mein).—This variety produces a loose bunch of leaves, which are narrow and of a dark purplish red colour. The roots are long and narrow, and somewhat irregular. The flesh, when cooked, is fine-grained, a rich deep colour, and an agreeable flavour, but less sweet than some other varieties. We must consider this second-rate in quality.

NUTTING'S SELECTED DWARF RED (Nutting and Sons).—Leaves 12 inches long, neat and tapering, and inclined to spoon-shape, crimson-purple colour. Roots medium size, tapering, neat; a fine crimson-purple colour. When cooked, of a fine close texture, sweet and good. This is one of the best of beets when true. We have had some samples very mixed; that from Messrs. Nutting and Sons was perfect.

PERKINS'S BLACK, the same as *Whyte's Black*.

PINE-APPLE SHORT TOP (Barr and Sugden).—Leaves small, dark purple, the stems tinged with orange; roots small, neat, slightly furrowed. When cooked, the flesh is of a deep crimson colour, tender, sweet, and good, and finely textured. True samples of this variety produce the most uniform roots of any; it is certainly one of the best varieties in cultivation, but does not make a large return in aggregate bulk of roots.

RUBY CASTLE (Wood and Son).—Leaves broad, wrinkled, and a fine blood-colour; roots medium size, symmetrical. When cooked, a fine deep crimson colour, fine-textured, sweet, and agreeable. One of the best.

ROUGE DE CASTELNAUDARY, a mixed stock of *Cattell's Red*.

SANG'S DWARF CRIMSON (Wood and Son).—Of the same strain as Nutting's, but inferior to it.

SEA KALE, or SILVER BEET (Sutton and Sons).—This is a Brazilian beet, producing large, oblong, bright green leaves, which are borne on long thick white stalks, which are glossy and like alabaster. The midrib and principal veins of the leaves are of the same character as the stalks. The root consists of a few stout whitish cord-like divisions, which are of no value. A few rows of this variety in the kitchen garden have a very elegant appearance; but unfortunately there appears to be no good reason for giving it a place in the garden, for it is as nearly useless as possible. If turned to account, all the white stalks and midribs of the leaves are to be boiled and served up with melted butter in the same way as seekale. It is possible to eat it when so prepared; but it usually acquires a dark colour in the process of cooking, and is not so good in flavour as to compensate for its ill appearance. Nothing can be more tempting when growing, or more disappointing when cooked. We have tried earthing up the stalks, but without any appreciable improvement for the table.

SPINACH BEET, or PERPETUAL SPINACH (Sutton and Sons).—This, like the last, produces an insignificant root, and is grown for the leaves only. These are of a bright grass-green colour, elongate triangular, on short stalks, and are very abundantly produced. When selected so as to avoid both the youngest and oldest, and cooked in the same way as spinach, this forms an excellent dish, in praise of which it would be difficult to say too much. On hot dry soils, and in the hottest part of the summer, when spinach cannot be prevented running to flower and becoming tough, this continues to supply an abundance of its tender beautifully coloured leaves, which have that peculiar combination of buttery and bitter flavours for which spinach is so much prized. We gathered good dishes of this spinach as late as the 30th of November last, the October frost not having had the least effect upon it.

SUFFOLK RED (Wheeler and Sons).—Dwarf and compact in growth; leaves elongate triangular, on long stalks, wrinkled and glossy; a fine bronzy purple colour with bright crimson tint. Roots medium size, very neat, in form approaching to elliptical, the thickness increasing downwards from the crown and then tapering off regularly. When cooked, the colour is a brilliant deep carmine; flavour excellent. This is the most distinct and brilliant in leafage, and if beets are grown as bedding plants, Suffolk Red will produce a better effect than any other variety.

WHEELER'S EXTRA FINE (Wheeler and Sons).—Growth irregular and decidedly ugly, the leaves being in a loose tuft and the crown spread out in an objectionable manner; root medium size, looking as if shrunk, being much contracted below the crown and more or less forked. When cooked, this is a tender, delicately-flavoured, and richly-coloured beet. Its want of symmetry is a great defect.

WHYTE'S BLACK (Sutton and Son).—Leaves large and broad, dark dull green. Roots very large, slightly bulging below the crown. When cooked, darker in colour than any other variety, fine-textured, and very good flavour. A good variety for market, but not suitable for garden cultivation.

The following are the best: *Cattell's Purple Topped*, *Dewey's Short Topped*, *Pine Apple*, and *Nutting's Selected Dwarf*. For market purposes: *Common Red*, *Whyte's Black*, and *Suffolk Red*. S. H.

ON THE PRACTICE OF UNNAILING WALL-TREES.

In remarks on the practice of unnauling wall-trees in your issue of Nov. 30, in so far as they refer to peaches and nectarines, or, in fact, any other kind of stone-fruit trees, Mr. McElroy gives his opinion founded on experience. Being one of the advocates of the unnauling system, I am induced to offer a few fragmentary remarks in favour of it; and as your able correspondent has called attention to the subject, it may be advisable to ventilate the so-called theory a little further, and bring before the readers of the Magazine a number of other reasons why trees should be unnailed annually. Nevertheless, others may be induced to carry both sides of the question into practice, and, for the sake of experiment, take two trees side by side. And first, I would say, for the tree to be treated on the unnauling principle, I would most emphatically decry the use of shreds altogether. It must be commonly observed by every one having anything to do with trees where the use of shreds is still adhered to, that under every shred the shoot looks pale and sickly for want of light and air. Another reason, and a very important one, is that shreds mostly consist of woollen materials, and those generally of a very dark colour, and attract more heat when it is hot; they also attract and retain an undue portion of moisture to the shoot at the point of contact; consequently the tree and all its branches are for many weeks in winter bound, as it were, with as many ligatures of ice. I would ask Mr. McElroy, does this practice

benefit the tree or otherwise? I argue that it is not only essential, but absolutely necessary, that they be not only stripped of the major portion of their shreds, but that the shreds be consigned to the flames, to be no more seen or heard of. I would unnaul all peaches and nectarines on open walls from three to four months, beginning from first of December, tying the shoots in convenient bundles to stout stakes stuck in the ground eighteen inches from bottom of wall, stopping toward the top, so as to have all fruitful wood at least one foot clear of wall, and cover the wall immediately behind the trees with a coat of spruce-branches to prevent radiation, laying two or three at the same time on the ground just over the collar roots, to prevent evaporation. The neglect of this I hold to be one of the most productive sources of curl and green-fly in both peaches and nectarines. The spring shoots are invariably much crippled, consequently the midsummer shoots are all that are to be depended on for the following year, and those are often very imperfectly ripened. A good plan is to nip off the points of the shoots about the end of August. It will be seen I prefer renauling the trees about the end of March, when on most days a man may do three times the amount of nailing he can in either December or January; and as peaches and nectarines are nearly always worth a "groat a piece," the little extra time required in renauling ought to be given freely; and instead of using shreds, I recommend small string; and instead of cast-iron nails I would use round wrought-iron clout nails dipped in oil. I have often renailed peach-trees at even a later period than the above, when so full in flower that the pollen flew all round as if under a shower of gold-dust, followed by a splendid crop of fruit to boot. Now, with regard to the supposed objections Mr. McElroy has to the annually unnauling of the lesser shoots and branches, as affording a means for insect secretions in the vacant holes the withdrawn nails have left, the following mixture most effectually gets over that difficulty, viz., lime, soot, and cowdung in equal parts, with a little lamp-black and sulphur added, and applied in rather a thick state, filling every crevice; this mixture when dry is of a dull lead colour, and attracts but little, either heat or cold, radiation is intercepted, and of necessity the trees bloom later. Unwise or not, I think the careful cultivator ought to concentrate all the artificial means in his power to retard the blooming season. This is not to imply the crippling of the flowers, but that the more advanced period is more congenial to their healthful development.

Oulton Park, Dec. 5, 1867.

W. MUIR.

FORCING FRENCH BEANS.

Though this delicious vegetable can be forced about as easily as any operation connected with gardening affairs can be conducted, it will be found next to useless to attempt it unless proper means and a moderate supply of fire-heat are provided for that purpose; for the French bean, being a native of India, requires a genial temperature to bring it to perfection. In the north of England, in cold wet seasons, it is a difficult matter to produce good crops even in the middle of summer; therefore, unless a sufficient degree of warmth is provided, very little success can be expected; in fact, it had better be left alone, for it will only end in disappointment. Very few people build houses expressly for the purpose of growing this vegetable, so that the most suitable structure there is upon the place has to be devoted to it. For the earliest work, such as the first two or three successional crops, the pine-stove is the most suitable, and afterwards the vinery will do, if there is room and the plants can be placed so as to get an abundance of light as well as warmth. Generally speaking, a vinery is too much shaded for plants that require plenty of light to prevent their drawing up weak and leggy. I have seen the peach-house recommended for growing French beans in, but my opinion is that it is as ill adapted for that purpose as anything well can be. In the first place, there is not sufficient heat to produce a profitable crop until the end of the season, and on the other hand the beans are so liable to the red-spider that the farther they are kept from the peach-trees the better, for it requires the utmost amount of a gardener's skill to keep peach-trees from spider without bringing plants in contact with them that harbour it in every conceivable manner. So, again, where first-rate crops are expected they should be kept out of the vineries; but of course, where a little of everything has to be grown, and every available space has to be made the best of, the most suitable place of any is undoubtedly a nice little span-roof house about ten or twelve feet wide, with a walk down the centre. A brick pit with a southern aspect (if heated) is very well, but not so good as the house; for the plants cannot be examined so readily, and receive proper attention in all weathers, as they can in the house. I have grown very good crops planted out in pits where melons have been grown the previous summer. But, after all, I prefer pots; for during the earlier stages of development the beans can be grown in small pots or pans in one-third the space they occupy when they attain the full size. The most simple method, and one which will not fail to repay the cultivator for his trouble, is to sow the beans in forty-eight sized pots, say seven in each pot, and then one or two of the weakest can be drawn out; for five good strong plants are much better than a large number, and quite as many as a twenty-four sized pot will carry comfortably. When the beans are sown the pots should be placed as close to the glass as is convenient, to prevent their running up with long stems before they push out the rough leaf; and as soon as the pots are full of roots they should be transferred to

twenty-four size, which is the most convenient and suitable. The advantage of sowing in small pots and repotting into larger, consists in enabling the long stem to be lowered in the soil, which of course prevents the plants from falling about, and at the same time materially strengthens them. The soil is required both light and rich to grow them well. I find equal parts of fresh loam and rotten dung from an old hotbed to suit as well as anything; and to be used lumpy, of course. The pots will not require to be crooked, like pots used for potting hard-wooded plants; a few rough pieces, with a layer of rotten dung over them to keep the soil from mixing with them, is all that is required. In all stages of growth plenty of water at the roots will do no harm, and as soon as the plants are in a bearing state manure water twice a week will be highly advantageous to them; and they should be syringed once or twice a day, to keep red-spider and thrip down. But if these pests get hold of the plants, smoking with tobacco paper must be resorted to. If the thrip does not disappear through smoking, the best way will be to throw the whole lot away; and it may perhaps be as well to observe that the pots which the old crop has come out of should be washed thoroughly clean before the next lot is put in them, or else the new crop will be eaten up at once with spider, for it is next to impossible to keep the old plants towards the last entirely free from insects. As soon as the pods attain to the proper size for picking, they should be removed at once, for by remaining on the plants they only injure the younger ones. Where houses are employed solely for growing beans, the temperature should be kept at 70° to 75° by day, and about 60° at night, varying a few degrees according to the state of the weather; and on all favourable occasions air should be admitted, but it should be done cautiously, so as not to chill them. I have found *Sion House* or *Wilmot's Forcing* do best with me; *Newington Wonder* is also very good. A large collection is not required for forcing; one good kind is sufficient for anybody. Market growers appear to pay too little attention to the forcing of French beans; I should think they would pay as well as anything ever attempted.

GEORGE GORDON.

BEDDING PLANTS FOR A DISPLAY IN SPRING.

Flower gardening for the summer months, during the past quarter of a century, may be said to have attained very rapid strides towards perfection in relation to striking or glowing effect. So far is the application of its rules understood in connexion with the massing of the various plants that are adapted for the several purposes, and also the harmony of colours, that there is scarce an individual that has any interest whatever in the pursuit of horticulture but does to some extent understand its fundamental laws. This cannot create surprise when we remember the facility for obtaining the requisite knowledge, which the taste displayed in our public gardens and parks now affords in the way of first-class illustration of the art of bedding.

Having said thus much, may I ask, have we not ample room, where there is the space at our command, for improvement, by making the flower-beds more interesting and gay during the spring months, somewhat anterior to the period for summer bedding? It is true there are resources enough to be found among the lists of bulbous roots for the purpose; but I fear there are very few private establishments the proprietors of which would feel inclined to compete with the managers of our public grounds, in the expending of a sum sufficient to plant all their beds. Therefore it is expedient that the gardener should endeavour to make himself acquainted with hardy herbaceous plants that are useful for furnishing the beds with flowers during the spring months. As yet it is not too late to plant the beds where the requisite plants can be obtained. This paper has in some degree suggested itself by observing the preparation which my brother gardeners in proximity to me make for supplying the beds with flowers in the spring. One reason perhaps for their efforts may be, that their employers and families are absent some portion of the autumn and winter months, and therefore on their return they are anxious, in the earlier months of vegetation, to make the grounds as inviting as possible. Following in their footsteps (for they say example is better than precept), I am striving to be on a par with them; but I fear that we shall be somewhat in the rear next spring, owing to the remodelling of our flower garden, which has prevented me from transferring them so early as I should wish from their nursery beds. They say, better late than never, and it may be so with the few gleanings that I am about to submit. From it I hope materials may be collected for augmenting our future stores.

The most famous garden extant for variety of spring flowers is Cliveden, in Buckinghamshire, the seat of the Dowager Duchess of Sutherland, the formation and arrangement of which are due to Mr. Fleming, the head-gardener, and who has already published a work on the subject, the pages of which I cannot trespass on as I have never perused them. I will now draw on my own experience for a few practical notes.

Nemophila insignis.—If seed is sown now, it will bloom late in the spring. The drier the situation the better it will do during the winter months; damp is the greatest enemy it has to contend with in the winter. My plan formerly was to sow it in drills in November, the distance between which would enable me to plant out my summer bedding plants, if the *Nemophila* should not at planting time have completed its blooming season.

In a place where there are plenty of spare lights, a lot of beds might be sown with seeds of this plant, and early in spring they could be transplanted. There are a great many more varieties of annuals that are rich in colour and exceedingly attractive, which, if they are sown in the autumn, and afterwards potted singly into thumb-pots, and kept in cold frames or pits during the winter, and then early in the ensuing season transferred into the flower-beds, will produce a brilliant display late in the spring. The following species and their varieties are exceedingly well adapted for the purpose, viz., *Collinsia bicolor*, *Clarkia pulchella*, and the annual white variety of *Candydust*,

Gilia tricolor, &c. Perhaps one of the obstacles in the way of their general use, is that some of them may not complete their flowering season by the period the plants for summer and autumn decoration are required to be planted in their final quarters. The practice of double cropping has been adopted with success in the kitchen garden. Why should there not, then, be the same attempt in the flower garden, where opportunities may be presented by admitting sufficient width in the rows at the time of planting or sowing, so as to allow of the usual bedding stuff being planted betwixt them?

The *Yellow-flowering Pansy* must be considered as the most valuable dwarf plant we have for spring or summer blooming. For several months past, during the present year, I have been very much interested with the never-failing succession of flowers which has been produced by a border of this pansy, which was planted as an edging to a large bed in a garden cultivated by my neighbour, Mr. Burley, the respected nurseryman. Although the bed is situated several yards distance from the spot where I can view it, yet it forms a very bright spot in my prospect. For general culture it cannot be too strongly recommended. In addition to this we have also the *Blue Pansy*, a very beautiful variety for spring decoration. Then, again, there is the *Purple-flowering Pansy*; but for general usefulness the two former have my choice.

Pink and White double-flowering Daisies.—These delightful harbingers of spring vegetation were to be found cultivated in most of our gardens when I was a lad, but something seems to have almost drifted them from us. Perhaps the cause may be attributed to the rage which has existed within the last few years for an increase of summer and autumn flowering bedding plants. But of late I have been somewhat pleased to renew my acquaintance with them in my present locality, and I hope that in the future I shall be enabled to give them that encouragement which they deserve. Although they are easily propagated by division, yet during the summer months they require liberal treatment, a moist or shady situation being desirable, as the direct rays of a hot sun will burn them up.

The *Double Yellow* and *Dark Wallflowers*.—These, like the preceding plants, seem to be quite overlooked by the present generation of young gardeners, in the desire to increase their stock of summer bedding plants. What is more useful for cut blooms than the double yellow? And it is remarkably showy. They are not so well adapted for the bed as the border, for unless the plants are well established they will not bloom so abundantly. The weather, if very severe, is apt to injure them, so that it is advisable to shelter them in pots in a cold pit or frame during the winter months.

Some of our hardy early spring-flowering plants of dwarf growth make excellent edgings round those beds that are planted with bulbs, as the perennial *Yellow Alyssum saxatile*, the Evergreen White Candytuft, *Iberis Sempervirens*. But they require to be prepared for the purpose as soon as they have done flowering, by division of the Candytuft, and the layering of the *Yellow Alyssum*.

Nor should we forget the lovely, snowy, white-flowered *Arabis alba*, of which too much cannot be grown where there is space available. This, with the former, can be readily increased by division of the roots. Perhaps the Candytuft is better propagated from cuttings. To get good plants for bedding in the autumn, they should be grown in nursery-beds throughout the summer months.*

Silene pendula.—This deservedly favorite plant still continues to be cultivated in abundance wherever spring flowers out of doors are in request; its dwarf habit and free-blooming qualities, combined with its bright pink flowers, constitute it an exceedingly effective bedding plant. The seed can be sown as soon as it is ripe. With this, as with similar plants grown for the same purpose, new seed is a boon. When the seedlings are strong enough, let them be pricked out on to any spare plot of ground a few inches apart, so that they can be afterwards removed with a trowel.

Myosotis sylvatica, or "Forget-me-not."—This beautiful and interesting hardy plant is worthy of all the care you can bestow on its culture for decorating the flower garden in the spring. It is a native of Switzerland. The British variety, *Myosotis palustris*, requires plenty of moisture. It is to be found growing in abundance along the banks of our streams and ditches in some localities, especially in the neighbourhood of Walthamstow, and the banks of the River Lea, in Essex. The treatment for garden culture is the same as that advised for the *Silene*.

Chieranthus Marshalli.—This is an admirable free-blooming plant. Its colour (yellow) makes it very attractive, and its flowers are very useful for bouquets or decorating the dinner table. It requires to be propagated early, that you may get your plants well established in pots for planting out at the required season.

Honesty, or *Lunaria biennis*.—As a tall plant for the flower garden in spring, its purple flowers, which are borne in clusters, are exceedingly effective. It is only fit for large beds or back rows, as it grows nearly three feet in height. It should be sown in the summer, and be treated similar to the Forget-me-not and *Silene*. It may be considered as a hardy biennial.

Nepeta violacea.—For planting either on slopes, beds, or rockwork, this hardy plant is in every way adapted; its myriads of lavender-coloured flowers make it very conspicuous during the spring and early summer months. As an herbaceous plant it is readily increased by division.

Hepaticas and their Varieties.—This is another class of plants whose presence is fast fading from our sight, and which in days gone by were wont to glad the heart of the beholder ere the first dawn of spring witnessed their unique red, white, and blue flowers emerging just above the earth's surface. The culture of both the double and single varieties of this plant, in my remembrance, was the pride of many of our fraternity whose days are now fast ebbing away. Large clumps of them might be seen growing in the flower border in various parts of the garden, or else in long lines as edgings, undisturbed, remaining in the same spot year after year; thus each clump would keep on increasing in bulk. Perhaps that, with a dry situation, was the secret of the success that followed its cultivation, as in its natural state it is to be found in the uncultivated woodlands of Switzerland. It is to be hoped that, in our desire to increase the number of early hardy flowering plants, many of the almost forgotten gems of horticulture will be restored to their proper sphere.

Polygonus.—For several years past I have annually purchased a packet of seed and sown them in April, and when up and sufficiently strong, have pricked them carefully into a nursery bed; by this means they have grown large and strong, and flowered very freely in the ensuing spring.

In bringing my notes to a close, I may have omitted many plants that are equally as valuable for spring gardening as those already mentioned; but my motive has been to promote the reaction that is taking place in the direction of spring gardening, and not to afford a complete list of plants adapted

* The best way to multiply the Candytuft and the *Yellow Alyssum* is by cuttings of the young growth soon after the flowering is over. We have a large stock at the present time raised from cuttings, and they are much stronger than seedlings.—Ed.

for the purpose. But I shall endeavour to collect material as opportunity affords for extending the interest of this most desirable branch of our profession. Perhaps my paper might have been more acceptable had it appeared in the latter part of October, as there can be no question that the sooner we get the spring flowers planted after the summer bedding plants have done their part, so much the stronger will they be in the ensuing season. However, to those who have not yet begun, if they only succeed in part next spring, the probability is that a newly-awakened zeal may induce them to accomplish great things in the future. Jno. F. McELROY.

Calendar.

WORK FOR WEEK COMMENCING DECEMBER 14.

Flower Garden.

FLOWER-STICKS are important items of garden furniture, and this quiet season may be well spent indoors, or in company with the furnace fire, in preparing a plentiful supply for next season. For ordinary purposes, the best flower-sticks are made by splitting what are known as four-foot double selected laths, which the bricklayer or lath-render will supply. These should be split and cut to proper lengths, the edges rounded off and the ends pointed, and then the whole should have two coats of paint. They will last longer if the pointed ends are dipped in hot pitch, which prevents their rotting in the soil. Flower-sticks of this sort are generally painted green, but they should be separated into two or three lots in sizes, and be painted two or three different colours, such as reddish-brown, green, and dark amber. These three colours will match nearly all the various kinds of stems of plants which the sticks may be used to support. The strong shoots of fuchsias that have been cut down in the open ground make excellent flower-sticks, and need no painting, because of their natural colour; the hardy fuchsia called *Riccartoni* makes first-rate flower-sticks, and the common Snowberry may be cut down for the same purpose—the stout rods trimmed for sticks, and the light ones put aside for use as pegs, for which purpose they are very tough and trustworthy.

Fruit Garden and Orchard House.

BUSH FRUITS to be propagated by cuttings of ripe stout shoots of last year, and the buds to be removed from the bottom of the cutting to within four inches of the top, so as to form a clear stem and prevent suckers. Lay on a thick coating of half-rotten dung between gooseberry and currant bushes, and in dry weather prick it in with a fork, so as to avoid injury to the roots. Raspberries to have a heavy mulch, which is not to be pricked in; any disturbance of their roots is a great injury. In small gardens, the best crop of currants will be obtained from standards, which are easily grown, and have a very handsome appearance when loaded with fruit.

FRUIT TREES to be planted with all speed; if delayed much longer, the next year's crop may be lost. Always trim away by a clean cut all bruised and jagged portions of the roots; place the original collar at the level of the soil, so that the tree is no deeper than it was before, and fill in with soil in a friable condition. No tree will prosper if the roots are puddled in with wet pasty earth.

TREATMENT OF UNFRUITFUL TREES.—Generally young fruit-trees on walls, especially pears and plums, and not infrequently peaches and nectarines, after being planted two or three years, get into such a vigorous and gross state of growth that their wood more resembles willows grown for basket-making than the firm and short-jointed wood which we look upon as the precursor of a plentiful supply of fruit. Then to depend on the pruning-knife, as usually applied to the branches of such trees for subduing their unruly luxuriance, is a fallacy; for whilst their roots riot in the full enjoyment of a fresh-made border, without check or hindrance, so long will they continue to renew their gross and unfruitful growths, as they penetrate deeper year after year, getting further from the influence of the sun and air, and if the soil is wet, the cultivator looks in vain for produce other than canes for staking his flowers with, and even on a dry well-drained soil they often are several years in outgrowing this over-luxuriance; but apply the knife to the root, in conjunction with the spade and digging-fork, carefully removing the soil from their roots, lifting one by one all the fibrous roots towards the surface, and those that take a decided downward direction into the subsoil get up if possible, and place them horizontally, or, if that cannot be done, cut them entirely through. If, however, the tree be not too large, say not more than four years planted, they will often be benefited by being entirely lifted, placing them again in the hole after the bottom is levelled, but if the soil is stiff or wet, fill up the hole, mixing a portion of porous soil or charred refuse during the process, and then place the tree on the surface raising a small hillock of soil over the roots, and upon that place a mulching of litter, in order to protect them from winter's cold and summer's heat. Now is the very best time of the year for proceeding with the operation, as the trees have yet sufficient vital force left to re-establish themselves before they shed their leaves, and the sap becomes inactive. If performed skilfully, this will generally have the desired effect of throwing the tree into a moderate state of growth, which will result in well-ripened fruit-bearing wood, but if unskilfully or carelessly done, the result may be the loss of the tree. Remember, a tree can no more bear to be ruthlessly torn up than a man can bear to have his feet torn off. Watering will be required both at root and over the branches, and they must not be forgotten in that respect in the following summer. It is a very common complaint that pear-trees in buildings produce no fruit, save a few at the extremity of their branches; the cause of this may most generally be traced to the want of sun and air to the root: either their roots are paved over, and by that means kept in a damp and cold soil, or they are got deep into a wet subsoil, from which they draw a too free supply of crude watery sap for the tree to properly digest and assimilate. Much might be done for such trees by raising the pavement, if any, and getting up some of the roots towards the surface, cutting through tap-roots, that is, those that proceed immediately from the tree in a downward direction. Replace the earth removed in so doing by fresh, and if it must be so, lay down the pavement again; but such trees are generally badly furnished with small fibrous roots. Care must be taken not to cut too many of the large roots through at one time, lest the balance between demand and supply, being too much interfered with, result in the loss of the tree. I reiterate this caution, lest the inexperienced in such matters, being too ardent in their desire to rectify one evil, should fall into another. In cases where very old or large trees are to be dealt with, it is best to take two years to the work, and do one half at a time, or, in the first instance, to dig a hole, three feet square and three feet deep, directly in front

of the stem of the tree, and at about three yards from it. Then proceed to dig at the same width and depth towards the tree, taking care of all roots met with in so doing. By this means the very large roots that proceed from under the stem downwards may be got at and cut, whilst those that spread on either hand, in a more horizontal direction, will be preserved to cater for the tree. If after a year the excessive vigour be not sufficiently restrained, it may be proceeded against on either side in the same manner. On again filling the holes, a portion of fresh soil should be used, and such as is dug by roadsides, being gritty and porous, makes an excellent material for the purpose; but as unfruitfulness sometimes proceeds from debility and weakness, let me say that in such cases rich soil and thoroughly decayed manure should be lightly dug in among the roots with a fork, mulchings of horse-dung laid over them, and in spring and summer waterings of warm liquid manure should be given, until sufficient vigour is obtained.

Greenhouse and Conservatory.

GREENHOUSE to have as little fire-heat as will be safe, and to be kept as dry as possible. On the occasion of a sudden frost, there is a tendency to get up a brisk heat at night, and much harm is inflicted on plants by running the temperature up to 60° or more, and then leaving the fire to go out, so that by the morning they are exposed to a temperature of 35° or less. The amateur must endeavour to avoid such extremes. By a little watchfulness it may generally be known when frost is to be expected; the fire should then be lighted early in the day, and allowed to go very low at night, and be banked up the last thing, so as to burn slowly till morning.

CONSERVATORY.—It is undoubtedly desirable to keep the conservatory gay, yet chambers and other permanent occupants must not be forced into growth prematurely. Heat enough must be maintained to prevent mildew, and to allow of giving air freely; but the cultivator must endeavour to hit the golden maxim of keeping things safe and in order without pushing anything into growth before its time. If mildew occurs on valuable subjects, apply sulphur directly, but any nearly worn-out subjects that are becoming mouldy had better be got rid of altogether. Be very cautious in giving water; give enough, and not a drop to spare. A good time for a general watering is on those bright mornings when a west wind blows, and it seems as if spring had suddenly set in. Another time when watering must be generally attended to is when fires are going to keep out frost, for then it is that plants are likely to be dried up and irreparably injured.

HEATHS.—At this time of year, hard-wooded plants require a little extra care to protect them from injury by damp, undue fire-heat, and frost. A correspondent offers a few notes on the management of heaths, which appear to be well suited to this department. He says: Success with *Ericas* greatly depends upon three points, viz., air, water, and shifting, respecting each of which I will give the result of my experience in the cultivation of this very interesting tribe of flowers. It is a practice with many to nurse them too much, or, as the gardener would say, "coddle them," which is quite opposed to their nature, for they love air and light, and have little liking for artificial heat. I will commence upon their treatment at the present time and henceforth. Plants should now all be comfortably housed, and in such a way that they may have free ventilation. Watering must be performed with caution; always endeavour to give them rain-water, and take great care that they do not flag too much. On the other hand, never let them get soddened. The best time to water is early in the day, so that the damp will dry up before closing the house. If this is not attended to, mildew will appear, which is a very destructive agent, and must be checked by dusting with sulphur the parts affected. This is often produced by placing the plants too thick together, thus preventing a proper circulation of air through and between them. During the winter months care must be taken in giving air that they do not have too much when they are likely to catch easterly winds. At such times give it on the opposite side, if a span-roof house. Where a house is entirely devoted to *Ericas*, the frost just kept out is sufficient. When they have done blooming cut them back; if free-growing kinds, do not spare the knife. Where gardeners use the garden-shears they are termed barbarians, but not justly when used in moderation; when they have made their new growth gradually harden them off. It is a good plan where there is a pit vacant to put them in while they are breaking; after which shifting must be attended to. Plants that are in a growing condition at the roots require a good shift; see that the pots are clean, allowing a free drainage of broken crocks; on the top of the drainage put screenings of peat in a rough and lumpy state; fill up with a mixture of good peat passed through a half-inch sieve, with about one-fourth of silver-sand, and a moderate amount of fine pebbly grit; in this mixture they will root freely. In shifting do not allow the stem of the plant to be lower than what it has been previously, as they are apt to die off at that particular part. Fill the pot about one third with the compost; then with a round stick, about an inch thick, ram the mould quite hard, and so continue till finished. It is not requisite to keep them under glass after shifting, as it is seldom that drenching rains are prevalent then, but the more tender kinds will do best in a cold frame. As it may be useful to some, I would recommend a few good free-blooming kinds as follows: *Rogerminans*, *Gracilis*, *Vernalis*, *Autumnalis*, *Cavendishii*, *Hymalis*, *Sindryana*, *Lambertiana rosea*, *Colorans nana*, *Willmoreana*, *Persuluta alba*, *Propendens*, *Tubiflora*, and *Diosmæ capitata*. I find July a very good time for potting. Independent of what others may adopt, I feel persuaded that success will result from the adoption of the practice I have recommended above. It is a very bad plan to begin housing *Ericas* (in fact, any plants) too soon, for the nights during the early part of autumn are exceedingly beneficial towards promoting their vigour. The middle of October is a very good time to put them in their winter quarters; see that the surface of the mould is free from moss, &c. If this is not attended to, symptoms of ill-health will appear, as you cannot tell whether the plant is in want of water without riving the pot, which is no proof when the pot is small.

CAMELLIAS.—Extremes of temperature, moisture, or drought, will cause the buds to fall; and it will be as well now to see that all *Camellias* are really moist at the root, for sometimes after the root gets dry the water passes away on the outside of the ball, without any benefit to the roots whatever. A dry heat is very injurious to *Camellias* now.

ROSES must now be protected where they are much exposed to north-east winds. This is especially necessary in the case of standard tea roses, which in hard weather are often killed back to the work. If it is not thought advisable to take them up and pack their roots in earth in a shed, tie some haybands in and out among the shoots which form the head, so as to protect all the lower parts of the main branches, leaving the tops unpruned, to bear the full severity of the weather. The ends of the shoots may be killed back some inches, but the ripe and stout wood of the head will escape through being protected, and at the March pruning all the frosted parts will be cut

away. Dwarfs on their own roots are easiest protected by putting fern or straw loosely about them, and then laying a few heavy tiles or bricks over the roots; these keep the litter from blowing away, and preserve the roots from the effects of frost.

LESCHENAUZIA SPLENDENS.—The *Leschenauzias* take their family name from an eminent French botanist. They are evergreen shrubs from Australia, and belong to the natural order Goodeniads, and to the Linnæan, Pentandria Monogynia. They are greenhouse evergreens of very distinct and delicate growth, and the best of them are *biloba*, *areolata*, *formosa*, *oblata*, and *splendens*. Of these, *splendens* is the most showy, and the best habit; *biloba* is the next best, but more rambling in its growth. When making new growth the points of the young shoots strike readily in sand under a bell-glass in a moist bottom-heat. When struck, they should be potted in turfy peat, kept open with fine siftings of potsherds and silver-sand, but with no admixture of loam or manure. Use the smallest pots at first, and shift only as the roots require it, being at all times careful not to over-pot them. In winter they require an average temperature of 45°, with plenty of air, and when of good size will bear a temperature as low as 35° or 33° without injury. In summer they require to be partially shaded, and to have very free ventilation. The most important point in growing them is to stop frequently. If left to themselves, they ramble into very weedy shapes, therefore pinch out the points of the shoots of the young plants, and, after blooming, cut old plants back regularly, so as to induce a bushy growth for the next blooms. The stopping of young plants should be continued until they are quite bushy and symmetrical, and they should then be allowed to push into bloom. *Splendens* produces an abundance of its pretty scarlet blooms under the above course of treatment; but *biloba*, which has blue flowers, should be stopped before it is two inches high, and every shoot stopped again at the same length, as it is more inclined to ramble than the other.

STYPHELIA TUBIFLORA.—A useful member of the popular family of *Epacris*, which takes its name from *stypheos*, referring to the hardness of its wood. It is a greenhouse evergreen from Australia, and there are four good species in gardens, namely, *epacrioides*, *triflora*, *latifolia*, and *tubiflora*. The first and the last are the two best. They are propagated by inserting young shoots, taken off with a heel, in sand, in March and April; to be potted into small pots in sandy peat four parts, sandy loam one part, and charred turf one part. They must be stopped early, and again and again stopped, as the side branches push, till the plants are dense, bushy, and symmetrical. *Tubiflora* blooms in May, and produces a profusion of scarlet epacris-like blossoms at every joint, holding on in good condition till July. Whether in bloom or out of bloom, it is one of the most beautiful of greenhouse shrubs, and as easily managed as the commonest *Erica*.

LAGERSTREEMIA INDICA.—A greenhouse evergreen shrub from China, named after Herr Lagerström, a German. It belongs to the natural order Lythraceæ, or Loosestrifes. Propagated by inserting cuttings of small firm side shoots in sand under a bell-glass in spring, with a brisk bottom-heat. Soil, equal parts of turfy peat and turfy loam, and requires plenty of water at the roots and overhead, except when in flower, when the roots alone should be liberally watered. It has hitherto been usually grown in the stove, but its proper place is a cold greenhouse, where, under proper treatment, it produces abundance of its white or rose blossoms in August and September. There are two varieties, *Indica alba* and *Indica rosea*, and both are desirable. Success in management turns very much on the treatment after flowering, when it requires to be pruned, and allowed a season to rest, and to be kept then rather dry. It may be wintered in ordinary greenhouse temperature, and started in spring with a brisk heat to ensure plenty of bloom in the autumn. Managed as above, it flowers in great perfection at Kew.

CINERARIAS should be coming on nicely now to bloom. Those selected for the first bloom to be near the glass and in a warm place; those to be grown on must have a shift, and be kept as cool as possible. Green-fly must be kept down, and the cineraria grower has enough to do generally in this business. Plenty of air will be required by all alike, and regular supplies of water.

PELARGONIUMS must be as quiet as possible to be safe. A rapid fogging of the leaves will indicate that the house is too damp and cold; the formation of long delicate shoots indicates too much heat. The plants should be healthy, yet not growing; and in case of damp, a brisk fire in the middays hours will do immense good.

Stove and Orchid House.

ORCHID HOUSE.—The completest rest possible should be secured now to all orchids that ought to rest. There are a few orchids that never rest in a decisive manner, and many others are properly active at this time of year. But the golden rule for the orchid grower now is to keep things quiet till February, heat and moisture being reduced to the lowest possible minimum.

Forcing Pit.

MUSHROOM BEDS should be kept covered during bad weather with dry straw, and over that reed or straw hurdles, to throw off the wet and prevent entrance of frost. During mild bright days take off all the coverings, expose the beds to the air, and cover up again with fresh dry straw. This management will keep the beds in bearing, and without deterioration of the produce. Mushrooms frequently fail at this time of year owing to the cooling-down of the beds. It is impossible to maintain them in a bearing state at a temperature below 60°, and an additional 10° is an advantage. The safest order of procedure is to make up a fresh bed every month.

Replies to Queries.

Roses.—I have about fourteen new roses in pots, which I bought this autumn, and put into an ordinary cold frame, sunk them in cocoa-nut fibre, and put the glass over them. Will you kindly tell me, through THE GARDENER'S MAGAZINE, of which I am a constant reader, whether they ought to be watered at all during the winter, and how often? Also what is the best time to prune them? J. L.—[No doubt there are hundreds of readers, possessing new roses in pots under similar circumstances, equally anxious to know how to keep them. They require through the winter two sorts of attentions, one as to air-giving, the other as to giving water. We sincerely hope J. L. does not keep his constantly close shut up. In such weather as came on Tuesday and Wednesday last after a sharp frost, it would do them good to take off the glasses entirely for an hour or two, and then to leave a

slight gap for admitting air. In frosty weather they need not have air, and if the frost exceeds ten degrees it would be well to put a few mats or some dry litter over the lights. As to watering, they should never be dry at the roots; but how often water will be required it is impossible to say. Water them when they want it; and to learn the state of the soil in the pots, press a finger into it occasionally. When rather dry water freely, and give no more till rather dry again. This will be perhaps about once a fortnight for the next three months. At the end of February will be the proper time to prune these roses. It will be sufficient then to cut away a few inches from the weakest of the shoots, and to remove any shoots or parts of shoots that spoil the contour of the plants. Any extra long shoots cut back freely to range with the rest.]

Anxious.—Your stove plants that have not been well ripened should be kept for some time rather dry, and without pruning, in the fullest light you can place them in. Do not prune until they have had a long rest; then prune and start them.

Tacsonia Buchananii.—W. C.—This is a quite new species, a native of Panama, named in honour of its discoverer, Mr. Buchanan, horticulturist, of New York. It requires to be grown in the stove, is of vigorous habit, and flowers freely during the whole of the summer and autumn. The leaves three to five lobed, the lobes serrated; the flowers are three to four inches in diameter, consisting of ten petals of a bright vermilion colour; the corona has three divisions of the same colour as the petals. It was figured in the "Illustration Horticole" of June, 1867.

British Iris.—A correspondent points out an error in Mr. Chitty's paper on "Wayside Delights." The author speaks of *Iris fetidissima* as the only British species, whereas we have two, namely, this and *I. pseudacorus*. Any error is worth the trouble of correcting, but this is but a slight one, and it is a rare occurrence for Mr. Chitty to make a slip in any reference to British plants.

Gas-light.—R. H. G.—We know of no way to protect plants from injury by gas; that is to say, there is no specific to render the plants invulnerable; but perhaps it is an easy matter to remove them when the gas is lighted, and that is what we advise you to do.

Steam.—The feeding box had best be inside, but it need not be an eyesore. You have, no doubt, too much furnace power for the extent of pipes heated; it is in the reduction of the furnace power your remedy must be found, or in an extension of the pipes.

CATALOGUES.

W. CHATER, SAFFRON WALDEN. *Catalogue of Hollyhocks and Roses for 1868.*—No grower of hollyhocks can very well do without this list, so the announcement of it will perhaps be sufficient. The list of roses comprises the best of the perpetuals only. By the way, here are hollyhocks and roses side by side in a catalogue; it is not at all bad taste to put them side by side in the garden; the hollyhocks for a background to the roses. Try it.

E. B. SPENCE, DARLINGTON. *Catalogue of Flowers, Roots, &c.*—Contains good lists of bulbs; to which are added lists of new *Fuchsias*, new *Geraniums*, new *Verbenas*, select fruits, &c. Amongst the novelties is *Lobelia coronopifolia*, one of the finest of recently-introduced plants.

DOWNIE, LAIRD, AND LAING, FREDERICK STREET, EDINBURGH, and FOREST HILL, LONDON. *Descriptive List of Hybrid Gladioli.*—A well-arranged and very complete list, including the newest, the oldest, and the best in all the several sections, and a separate list of varieties suitable for beds and clumps.

J. HOUSE, EASTGATE NURSERY, PETERBOROUGH. *Autumn Catalogue, 1867.*—In this we have lists of bulbs, roses, fruit-trees, and other useful subjects in demand at this time of year, and a special notice of the new apple, Lord Burghley, which we have described in the "Garden Oracle," and can recommend to all who prize hardy dessert fruits of the very first quality.

HORTICULTURE AT THE PARIS EXHIBITION.—The visitor will derive a higher idea of horticulture in France from a visit to the Reserved Garden than he could get from days of travel along the poplar-lined *chaussée* and monotonous railroads; and "Capability Brown" could not do better than some of the French "layers out," who exhibit their plans of public and private grounds. The variety of shape in the hothouses and conservatories is not remarkable, and the Pavilion of the Empress is externally little short of the extremity of hideousness. What it may be inside is not given to many to say, as the *gardiens* is seldom there, and the door is locked. There are shows of roses, now fast falling, orchids, water-plants, azaleas, ferns, cactuses, aroids, gigantic pears, monster apples, rare and common fruits and vegetables, curious and vulgar trees and plants, exotic and indigenous; a restaurant, of course, and a platform for a band, all set in fresh greenward. A great artist, who calls himself an "undertaker of rocks," has constructed the most original aquarium, where the fishes are swimming over your head or resting on the transparent glass roof. You may observe, if you are resolute, strong, and patient, the manners and customs of many kinds of fish in the subterranean compartments devised by the clever gentleman, who will make you a roaring cascade, a trout stream, a lake, and any extent of caves and grottoes like those "shell strewn and consecrate of old to some Undine's love," in which Dido or Haidee sheltered of old, on most reasonable terms. It is just such a place as Parisians like, and the contemptuous critic, who might call it cockney, if he pleased, ought to pass a winter in an Alpine valley in order that he might appreciate the advantage of enjoying savage nature in a pleasant place not far from the Boulevards and the restaurants. The Reserved Garden is guarded by a dragon in the form of a 50c. toll, but it is nevertheless a most popular resort. Valuable dissertations are held over the fruit by rustic groups in blouse and mob-caps. The Grape Show is always in the hands of the country party, who discuss the merits of the bunches and the justice of the awards with an earnestness of conviction which is the more wonderful because it is founded on the evidence of a sense which, authoritative in many other respects, would not to the ignorant appear an infallible guide where touch and taste are not available to aid its conclusions.—*Times Special Correspondent.*

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a specimen copy free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, DECEMBER 21, 1867.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY is altogether a separate institution from the "United Horticultural Society;" the first may live when the second has ceased to be. It is some time since we had occasion to say anything respecting either of these bodies, and we now make occasion because we fear a good thing stands in jeopardy through keeping bad company, and we wish to direct the attention of our readers, and especially of gardeners, to the first-named of these societies as worthy of their support, and as calculated to be eminently beneficial to its supporters. One of the principal objects of the promoters of the United Horticultural Society was the establishment of a self-supporting provident fund especially adapted to the requirements and circumstances of gardeners. This part of its work is accomplished, and the Provident Society is thriving, and none of the differences that have unhappily arisen in the other society are at all likely to injure it, though they may for a time deter many from participating in its advantages, who, except for such dissensions, would ere now have associated themselves with it, to add to its strength, while properly seeking to benefit themselves. It will be remembered that the Horticultural meetings and exhibitions were highly successful up to a certain point, namely, the second Guildhall show in 1866. Then it was that, unfortunately, the society parted with its independence, compelled its best friends to feel ashamed of it, and entered upon a downward path. Even at that juncture, the mistake of associating the exhibition with a fancy fair might have been blotted out by united action and spirited enterprise in the cause of horticultural science. But it was not to be so. Things fell out in such a manner that some few who had rendered trifling services were compelled to leave in justice to themselves, and this disruption pretty well made an end of the affair. We repeat that the Horticultural Society has served its purpose: it first formed the connexion and drew the men together who were to lay the foundations of the Benefit Fund. Then it earned the means to pay the expenses of the foundation, and to start the society with money in hand. Then it became what it now is, or is not,—a thing or nothing, a shadow, a miserable remembrance; but it matters not if those who still call themselves the United Horticultural Society would take measures to extinguish the very name, and so leave a movement that is sound and good to make its way free from all these disagreeable associations. That is all we are aiming at in referring to past events. We wish to forget them, and wish them to be forgotten; that can only be accomplished by making a formal end of a society which virtually has come to an end already.

Now we say to gardeners of all ranks and classes, the UNITED BENEFIT AND PROVIDENT FUND is established on the surest foundations: the law protects it; its provisions are equitable and liberal; its financial scheme is, according to the highest authorities in such matters, perfect; it is for you, then, to make it a glorious institution and call it YOUR OWN. We forbear to enumerate the benefits it offers, as the rules are obtainable on easy terms, and in these columns the whole subject has been treated of at length. But it is due to you, we think, as to ourselves, that we should point out that the two societies are distinct from each other, and that the Benefit Fund is as self-supporting as a life assurance company, to which it bears a close likeness. Let not the miserable state of the once promising and flourishing U. H. S. deter any one who might otherwise be disposed to become a member of the Benefit society; for in the management of this there is no room for dissensions, the rules provide for all contingencies, and common sense and probity are the only requirements for its good management. It has the benefits of these good qualities in its committee of management, and we earnestly commend it to the gardening fraternity as admirably calculated to assist them in preparing against the day when sickness or disability may render a self-provided store a greater blessing than the most benign of charities.

To the employers of gardeners we have to say, that as the time has come when generous-hearted people loosen their

purse-strings, and bestow according to their means for the good of fellow-creatures less happily situated than themselves, this society is deserving of some help, for it not only secures the thrifty on the principle of assurance, but offers aid to the unthrifty and the unfortunate on the principle of Benevolence; for the unthrifty are not without virtues sometimes, and the unfortunate have ever a claim upon us. Patrons and honorary members pay to the benevolent fund of this society one guinea per annum, or ten guineas in one sum; the society numbers a few such already, and we shall hope that ere the "festive season" is over it will count many more; for assuredly the disabled, or, as we usually say, the "decayed" gardener is as well entitled to help as the decayed follower of any other craft. It may not be irrelevant or unseasonable to remind employers that gardeners, as a rule, are far in advance of the average intelligence and character of the industrial classes, and that their wages do not as a rule fairly balance their responsibilities and many trying labours. In plain truth, the gardener is not so well paid as he deserves to be, and this fact intensifies a claim that may be established on altogether different grounds. Apart from the wages question, there is so much of misery and mishap shared by all ranks and classes of the community, and every class has some special care for its own poor. Let us therefore consider, at this inclement season, the case of gardeners in want, and, through the United Horticultural Benevolent Fund, send our messages of kindness to them with a generous hand. To the young members especially of the horticultural community we say, Make provision at once for a rainy day, for youth and strength will pass away. To all who enjoy any share of the comforts of life we make an appeal in behalf of age, infirmity, sickness, and misfortune, reminding them that Christmas is at hand.

THE TASTEFUL ARRANGEMENT OF A FLOWER SHOW is one of the first essentials to its success. It is not enough for the general public, and it ought not to be enough for the professional visitors, to see well-grown plants, flowers, and fruits; a tasteful and effective grouping of the whole is imperatively required, and is not difficult of attainment. The grass banks and winding walks that contribute so largely to the perfection of the exhibitions of the Royal Botanic Society are too costly for any except a few wealthy societies, and are not to be thought of when we consider the possibility of improving flower shows generally. At Regent's Park, at the International Exhibition at Kensington, and at the last national gathering at Manchester, grass banks and mounds have vindicated themselves so effectually, that it is quite needless to say anything in their praise, and we only refer to them now in order that, in the attempt to improve exhibitions where such costly means cannot be employed, they may nevertheless be kept in mind as the sort of thing most desirable. To be strictly practical in these remarks, we must say first of all that as a rule the staging, the grouping, and the whole of the arrangements of provincial societies are objectionable, on the ground that as a rule they are ugly, and when not ugly, tame even to insipidity. Sometimes the plants are perched up so high that the visitor sees more of the pots than their occupants, and more of the timber supports than of anything else. The "line of beauty," which gardeners are expected to know something of, finds no development in the scheme of an exhibition; there is a tall stage in the centre of the tent, and some sort of table all round, and between them a walk for the visitors. Why it should be so angular and formal an affair we cannot imagine, unless it be to prove that man is a fallible creature, and apt sometimes to give to the line and rule the reverence he should reserve for beauty. It is not so much that one show is exactly like every other, that we make objections to the prevailing system, for the visitors do not all travel about and take an interest in exhibitions everywhere, but are chiefly concerned that their own should be a credit to the district, and a real help to the advancement of art and science there. Let us just imagine that we have a tent of a certain size to deal with. Mayhap, in the district may be a gardener or a carpenter of a designing (beneficently designing) turn of mind, and we go to him and ask him to design a set of tables and stages, not exactly of the stereotyped formal cut, but such as will

break up a mass of visitors into several streams, divided by variously shaped masses of plants and flowers, the grass banks and winding walks affording the basis of the scheme. We are rash enough to believe that in every town of this happy realm a man might be found without help of the crier who could accomplish this sort of thing, and in such a way, too, that, with the same timbers, the scheme could be varied every year *ad infinitum*, so as to be ever fresh and new, and afford an extinguisher to that particular (and rather large) class of superficial sight-seers who say, "If you see it once that's enough," and who actually believe that the same plants and flowers go every year to a flower show, and the same cattle and sheep to a cattle show. Of course these people are amongst the mistakes of nature, and ought never to have been born; but treasurers of horticultural societies profess to want their shillings, and the only way to get them is to give them something new every year. To turn the plants upside down and show the bottoms of the pots might do, but we rather incline to the plan suggested above of calling in the carpenter, and instructing him to plan a scheme which may be varied, and which shall not consist wholly of rectangular lines and figures.

But these hard straight lines that we complain of might be tolerated if we could but see the plants to advantage. It would be better in many cases if the stages were dispensed with, and the plants were placed on the ground in groups, and the visitors were allowed to circulate about them. If woodwork must be used, it should be very slightly raised above the ground-line, for, as a rule, we see a plant best when looking down upon it, and effective grouping cannot well be accomplished if the pots are on a level with the eye or above it. The next desideratum is to hide the timber, and give a seemly finish to all the mechanical details. How is this to be done? In the issue of the Magazine for July 7, 1866, we gave a sketch of a scheme for the imitation in carpenter's work of grass mounds and banks, and we here repeat it for the consideration of our exhibition friends during the quiet season.

Here is a very simple arrangement of staging, which conceals the pots and displays the plants to advantage. The sloping boards are covered with clean grass mowings, and the plants appear as if growing naturally on banks. It is with some gratification we call to mind that the proposal has been carried into effect in several instances, and in some cases (as our reports will show) the mere strowing of the stages commonly in use with short grass has very greatly improved the appearance of exhibitions. The best illustration of the proposal was that carried out by Mr. Crute, at the Guildhall shew last year, consisting of a raised circular bed in the centre of the hall, filled with chrysanthemums, primulas, and other cheerful flowering plants, with a groundwork of grass. Apart from certain fine specimen plants that compelled admiration, in spite of the pink calico that ruined that exhibition, Mr. Crute's

rich bed, formed on a framework after the scheme of the foregoing figure, and filled in with grass mowings, was the only distinct and pleasing feature of the whole exhibition. We were greatly pleased to observe at the splendid exhibition of chrysanthemums held lately in the Artillery Hall, Stratford, that our suggestion was in part carried out by the formation of a central table in two levels, as in the accompanying figure, where the pot-plants forming the centre line, with flowers on either side, were so placed that the plants were seen in their entirety and the pots were wholly hidden. Grass mowings are

scarcely available in the middle of November, and so as respects chrysanthemum shows our proposals must necessarily be modified. It is very strange that gardeners as a rule should forget the best part of their knowledge of pictorial effect and harmony of colours as soon as they set about getting up an exhibition of plants, and labour rather to render it an exhibition of unplanned deal and flower-pots. Perhaps, if we have patience, things will mend, and so for the present we will say no more about it.

CALIFORNIAN WINE.—In California grape-vines are planted about one thousand to the acre. In four years each vine yields half a gallon of wine, or five hundred gallons to the acre. In 1865, 40,000,000 vines were planted in California. The yield in 1866 was 8,000,000 gallons, and the value about 6,000,000 dollars.

MEAT BISCUITS.—The *Melbourne Argus* of September 26th says: "Mr. M'Cubbin, baker, King Street, who supplied meat biscuits for the Burke and Willis expedition, has sent us samples (which are very good) of such biscuits, both plain and sugared, made by a new process which he has patented. The matter is important at present, seeing how very large a number of sheep are likely to be boiled down this season for their fat alone. Mr. M'Cubbin informs us that he only requires the substance of the meat without the fat. He finds that he can, with a boiling-down establishment or a slaughtering company, make bread containing equal proportions of animal and bread stuffs, at a small cost over that of common cabin and navy bread. He has made samples that contained no less than six parts of meat to one of flour, and has flavoured them with vegetables and spice necessary to make any kind of soup. He can also make this biscuit with such a proportion of meat as to keep for years." It is one of the great problems of the time, how to convert surplus meat in Australia and South America into a saleable article in England. The manufacture of Leibig's Extract is already accomplishing one part; surely, the manufacture of meat biscuits would complete the solution of the problem.

EXHIBITIONS ANNOUNCED for 1868. The following are the dates of the intended exhibitions of the Royal Horticultural Society, and the Royal Botanic Society:—

- March 14, R.H.S. Hyacinths and other spring flowers.
- " 21 to 28, R.B.S. Hyacinths and other spring flowers.
- April 18, R.H.S. Forced roses and other spring flowers.
- May 9, R.H.S. Azaleas and other spring flowers.
- " 27 and 28, R.B.S. First great exhibition.
- June 1 to 13, R.B.S. American plants.
- " 2 to 5, R.H.S. First great show.
- " 16 and 17, R.H.S. Special prize and pelargonium show.
- " 17 and 18, R.B.S. Second great exhibition.
- " 30, R.H.S. Rose show.
- July 1 and 2, R.B.S. Third great show.
- " 16 to 21, R.H.S. Provincial show at Leicester.

TUESDAY MEETINGS of R.H.S., 1868.—Jan. 21; Feb. 18; March 4 and 18; April 1 and 15; May 6 and 20; June 3 and 17; July 1 and 15; August 5 and 19, Sept. 2 and 16; Oct. 7 and 21; Nov. 17; Dec. 15.

LECTURES at the ROYAL BOTANIC GARDENS, 1868.—May 15, 22, 29; June 5, 12, 19, 26; July 3.

UTILIZATION OF SEWAGE.—After a careful consideration (says the *Journal of English Agricultural Society*), the following practical conclusions may safely be deduced from these experiments: 1. That by the use of sewage a very great increase (varying from two to threefold according to the season) may be obtained in food, milk, or value of the milk. 2. That a yet larger increase may be anticipated from the application of sewage systematically over large tracts of average or sandy land, than was obtained from these pastures of naturally good feeding quality, and consequent higher natural yield. It is estimated that with 5,000 tons of sewage judiciously applied to Italian rye-grass or meadow land properly laid down to receive it, an average grass produce of not less, and perhaps more, than 1,000 gallons of milk per acre per annum might be anticipated, which, at 8d. per gallon, would represent a gross money return of £33 6s. 8d. Or, to put the result in another way, it required, according to circumstances, the consumption of between 5 and 6 tons of grass for the production of 1 ton of milk; and if we reckon 6 parts of grass for one of milk, and 30 tons of grass per acre, this would give a gross return in value of milk at 8d. per gallon something over £37 per acre, or of about 25s. per ton of grass consumed.

AGRICULTURISTS AND THE CO-OPERATIVE PRINCIPLE.—A meeting of agriculturists was held in the theatre of the Islington Literary and Scientific Society, on Wednesday, for the purpose of discussing the propriety of introducing the principle of co-operation into agricultural business affairs. The meeting was convened by the Agricultural and Horticultural Association (Limited), an organization whose main object is the establishment and spread of agricultural co-operation. Mr. T. Hughes, M.P., presided, and advocated the principle of co-operation. An interesting discussion followed.

A FERN-LEAF wreath, with imitative coral appendages, is brought out by Mr. Goodman, of the Strand, as a Christmas household decoration. The effect is good.

CATALOGUES.

LAIRD AND SINCLAIR, DUNDEE. *Descriptive List of Gladioli.*—In this excellent catalogue the varieties are classified according to their predominating colours, which increases its usefulness. It is a full list, and includes the newest kinds.—*Select Catalogue of Roses.* A choice but not a meagre list, for it comprises all the classes, and the best varieties in each.

SUTTON AND SONS, READING. *Amateur's Guide for 1868.*—This increases in bulk and goodness every year. It is crammed full of useful information; and in the lists of various kitchen garden and flower seeds many matters of interest crop up to render the book everywhere something better than a trade circular.

THE RONDELETIA.

I am unable to say whether the scent sold as *Rondeletia* at our shops is obtainable from this shrub or not, but certain it is that some of the kinds emit a most delicious and grateful perfume. In point of beauty, as regards its flowers and its desirability for making a handsome specimen, it can successfully compete with any stove plant with which I am acquainted. But it is so often seen in such a neglected manner—poor straggling plants, instead of large, handsome, well-shaped specimens—that I am induced to offer a few remarks upon its management. In doing this, I shall dwell as briefly as I can upon the cultural directions, with a due deference to its intelligibility. Most of the species are naturally of a straggling habit; therefore, when the plants are intended to be grown into large specimens, they will require careful culture and training in the young state, for it is well known to plant growers that unless hard-wooded plants are taken in hand from the commencement of their existence, which we will suppose begins on their leaving the cutting-pots, it is a matter of the greatest difficulty, to say nothing about impossibilities, to get large handsome plants such as those which were properly trained from the beginning. The propagation is not a matter of very great difficulty, for the young half-ripened shoots will strike readily enough if inserted in sand and peat, covered with bell-glasses, and the pots plunged in a mild bottom heat of about 75°. They must, of course, receive proper treatment as regards shading, watering, and other little matters well known to everyone who has any knowledge at all of plants and plant-growing, and which will be entirely unnecessary for me to dwell at length upon. We will suppose the plants to be well rooted and ready for potting off. Sixty-sized pots will be found to be the most suitable to put them in, and fibry peat and sand the best soil to use for that operation. As soon as the plants are established in these small pots, their tops must be nipped off about three or four joints from the base. As soon as these eyes are started and the young shoots grown a couple of inches in length, the pots will generally speaking be found to be full of roots, when the plants must be shifted into forty-eight or thirty-two sized pots, according to the strength and vigour of each individual plant. In this shift use a little loam in addition to the peat and sand, in the proportion of one part loam to three of peat. As the plants progress they must be stopped and trained, so as to get a good foundation as it were to build the plant upon. After they are shifted into twenty-fours, which will most likely be the following spring, they will require training neatly. A globular shape is preferable, and it is good practice to top only those shoots which are too luxuriant, and are likely to rob the weaker ones. After they are out of the forty-eights, a larger proportion of loam should be added—say one-third part to two of peat will be a good mixture—and plenty of clean crocks broken to the size of small hazel nuts, in addition to a good sprinkling of sharp silver sand. A little charcoal broken finely is advantageous in assisting to keep the soil open and porous; but at the same time I do not attach so much importance to the charcoal as to advise going to a lot of trouble and expense to obtain it; but if it can be got at easily, it is as well to use it. Both peat and loam must be lumpy, for finely-sifted stuff, or soil deficient in fibre, is of no use whatever if fine healthy plants are expected; for the roots are rather delicate, and unable to run in close soil, or that which soon gets sour. As some kinds of peat are apt to acquire a degree of sourness ere the pots are filled with roots, it may perhaps be as well to remark that at all stages of growth the pots used should be thoroughly clean and well drained with rather small crocks, so as to carry the water away readily. In the middle of summer when they are growing vigorously, they will take a pretty liberal supply of water at the roots; but even then, as well as when the plants are at rest through the winter, the greatest caution is necessary; for if the roots are over-watered, it will be impossible to keep them healthy, and, on the other hand, if the roots suffer from drought, some of the kinds will soon shed their leaves, thus destroying the beauty of the plant for a long time. In giving this caution, I do not for a moment say that this plant is more susceptible to injury from excessive watering or drought than others of its class; for all hard-wooded plants, more particularly large specimens, have to be watched narrowly to keep them going on favourably.

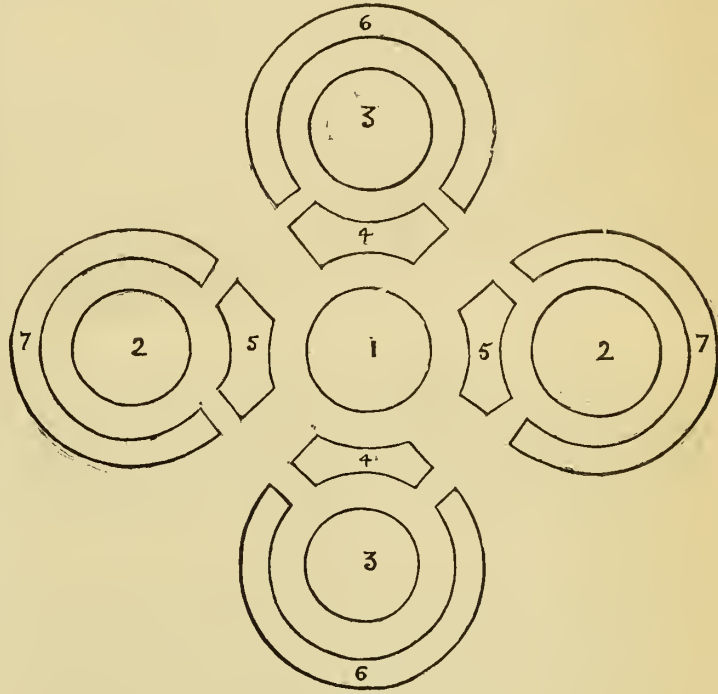

Like other stove plants, the *Rondeletia* requires syringing occasionally to keep the pests which usually infest it in subjection. They must also be kept free from scale by hand-washing when necessary, for the syringe has very little power over the scale. Nothing betrays so quickly a want of skill and attention as to see plants eaten up with insects. As regards the best kinds, I shall name three only, and those are the most popular: *R. speciosa* and *R. speciosa major*, both flowering in April, with nice trusses of bright orange-scarlet

flowers, which are abundantly produced. *R. versicolor* is also a very fine kind; it blooms in February and March, with large trusses of a light pinkish colour. This is fine for bouquets, and is very sweetly scented. GEORGE GORDON.

THE BEDDING OUT AT "THE LAURELS," TAUNTON, 1867.

In the spring of the year, when my friend Mr. Hibberd was on his western tour, he favoured me with a visit. I promised to communicate to the readers of the Magazine some details of the planting of the geometrical and other beds in my flower garden, a sketch of which will be found in the Magazine of the 1st of June last. I now gladly redeem my promise, with a hope that my brother amateurs may find in my plans something worthy of a trial in their arrangements for next year. If the reader who is really interested in this subject will turn back to page 232 of the Magazine for the 1st of June, 1867, he will find the sketch just referred to. It is drawn to a scale of 1-18th of an inch to 1 foot, and is therefore too small to be reproduced for the illustration of the particulars now to be given. I have therefore supplied some rough (but I hope useful) diagrams, which will be best understood by comparing them with the sketch at page 232. It should be here remarked, however, that since that drawing was made I have carried out a few alterations, there being now a conservatory attached to the dwelling-house, and a series of three beds on the small lawn adjoining the house, the position of which is near the rockery and trees, marked G on the plan referred to.

The border on the left of the large design (which, by the way, has for a background a dwarf wall covered with ivy) was planted as follows: Line of *Cineraria maritima*, line of *Iresine Herbstii* (which only looked well very late in the season, and will not be used again); next a row of *Cloth-of-Gold Geranium*, followed by a band of *Lobelia speciosa Indigo Blue*, and edged with *Cerastium tomentosum*, next to a narrow strip of turf, which separates the border from the walk. I consider this arrangement would be much improved by substituting *Amaranthus melancholicus* for the *Iresine*, and *Arabis variegata* for the *Cerastium*. The colouring was certainly chaste, and was much admired.

Group of Flower Beds, A.

Star-shaped Bed, F on the plan (see page 232).—A centre of *Centaurea ragusina* (syn. *eandidissima*), one large plant, from which radiated lines of *Amaranthus melancholicus* (kept in bounds by frequent pinching). The spaces were filled in with *Geranium Mrs. Pollock*, a band all round of *Lobelia speciosa*, edged next the grass with *Cerastium tomentosum*. I was so much pleased with this, and the numerous visitors praised the arrangement so highly, that I have determined to repeat it next year, and to plant the bed marked E precisely the same, with the exception of Mrs. Pollock, for which will be substituted *Variegated Geranium Flower of Spring*, and I may even be tempted to give *Iresine Herbstii* "one more trial," using it in place of the *Amaranthus*. I should here add a few words to those who cannot grow Mrs. Pollock. It failed with me until I deeply trenched the soil in early winter, and gave it a good dressing of stable manure, and in the spring, as soon as the winter bedders had been removed to their summer quarters, it was again dressed, but this time with well-rotted manure and a little leaf-mould. No geranium could have grown more vigorously, and the markings of the foliage were beautiful in the extreme; indeed, it grew so well that I was enabled to secure upwards of a thousand strong cuttings from this one bed. The old plants were, of course, taken up and potted off for the winter, from each of which I hope in the spring to take three or four more cuttings.

Circular Bed, D.—This was filled with *Coleus Verschaffeltii* edged with *Centaurea gymnocarpa*, as described in my paper on "Bedders" which appeared in the Magazine of 23rd Nov. last. We recommend those with whom the *Coleus* has failed to try the plan which we succeeded so admirably. It will amply repay the trouble taken. I should also add that as soon as the plants have taken hold of the soil and begun to grow, the discoloured leaves, of which there will sure to be a few, must be carefully removed.

Circular Bed, C.—In this the centre was formed of *Amaranthus melancholicus* surrounded by a broad band of *Calceolaria aurea floribunda*, followed by one of a similar width of *Viola cornuta*, and edged with *Stachys lanata*, kept

within bounds by frequent stopping. This would be improved by substituting for the outer edging either *Dactylis glomerata* var. or *Arabis alpina* var. I would also for *Viola cornuta*, which is both uncertain and the bloom weak in colour, substitute either *Purple King Verbena* or *Lobelia speciosa*.

Star Bed, E.—Centre of *Flower of the Day Geranium*, followed by *Geranium Brilliant*, edged with *Purple King Verbena*, and a band next the grass of *Cerastium tomentosum*. This was in every respect good.

Geometrical arrangement, A.—I have supplied a sketch of this; the scale is 1-8th of an inch to 1 foot. The centre circular bed (1) was filled with eight or nine strong plants of *Variegated Japanese Maize*: this was so highly spoken of in the spring catalogues, that I had great care taken to secure good and well-variegated plants, but I was even more disappointed with this than with the *Viola*. The plants grew strongly enough, but never looked even decent. The leaves became ragged and unsightly, and the whole were eventually removed and replaced with a specimen of *Dracaena Australis*. I have seen this (the *Maize*) growing in several places in this neighbourhood with much the same result: it certainly is not a "bedder." Circular beds (2, 2), *Ageratum Prince Alfred*, and (3, 3), *Viola cornuta*, which served me so badly, and so went to the rubbish heap. (4, 4), *Geranium Cybister*, and the pair beds (5, 5), *Geranium Christine*. The horseshoe beds (6, 6), *Geranium Lady Middleton*, which,

filled with *Lobelia Indigo Blue*, edged with *Echeveria secunda glauca*. The arrangement of this, though simple, was greatly admired.

I must now refer to the beds that have been formed since the plan at page 232 was drawn. These are on the small lawn adjoining the dwelling-house, and in form and arrangement are represented in the annexed diagram. The circular beds (letters J, J) were planted with *Geranium Lord Palmerston*, edged with *Geranium Bijou*. The large oblong bed (K) had for centre *Dactylis glomerata* var; on each side of it rows of *Amaranthus melancholicus*; next, on each side of the last, *Golden Chain Geranium*, followed by a band all round of *Lobelia Indigo Blue*, and finally edged with *Variegated Chrysanthemum Sensation*. This was perfect, and I do not suppose that, vary it how we may, we shall beat in this particular bed the planting of 1867.

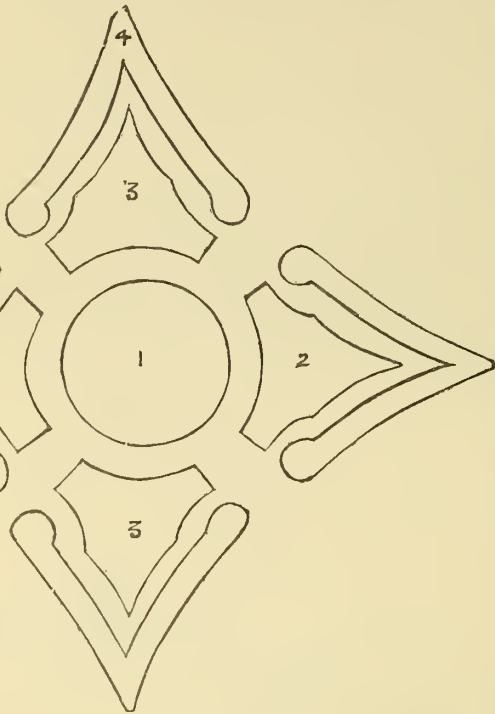

The Laurels, Taunton.

J. B. SAUNDERS.

WRINKLES FOR ROSE GROWERS.

Many a laggard is caught with uncompleted arrangements by King Frost, who never fails to punish procrastination by plentiful crop of doubts and fears, and apprehensions of failure in our cherished projects. When once the tyrant has set down his iron foot, who can tell when he will think proper to take it up again? We may be weather-bound for weeks. Our plantings and removals delayed till the prospect of summer blooms becomes an enigma difficult of solution, and all because of neglecting to seize father Chronos by his top-knot at the proper opportunity. To the victims of such unfortunate delays, however, there are still crumbs of comfort in the idea that ingenuity may in some degree repair the consequences of neglect; so let us see how to effect such a desirable consummation. The remedy is in manure. Where planting has been deferred, from whatever cause, some such course as the following must be pursued. Obtain a good supply of warm litter, the shorter the better, and having determined upon the situation where plants are to be placed, lay a good circle of manure, nine inches in depth at least, upon the soil. The ground under this will be impervious to the hardest frost, and whenever circumstances are convenient for planting, by simply removing the aforesaid manure the ground beneath will be in admirable order for receiving plants; afterwards the manure may be returned over the surface in the shape of a luxuriant mulch, to be worked in during the spring.

Those rose growers who wish to obtain fine blooms may adopt the following plan even yet, although it is somewhat late. Wherever roses are to be planted, let a foot or so of the earth be removed, and fill the cavity so produced with a couple of gallons of liquid manure—the richer the better. This will soak into and permeate the soil, forming a rich reserve of nutritious food, for roses, like the typical aldermen of old, love good living, and revel in strong liquors. At the end of February or commencement of March, weather permitting, the trees may be planted in the prepared hollow, filling in, in juxtaposition with the roots, a mixture of fat loam, roasted sods from heavy land, strong pig-manure, and a shovelful of bones. With such treatment of his plants, the would-be exhibitor need not fear that his roses will be passed disdainfully over by the judge's eye for want of substance, for they will be, as the knights of King Arthur's round table declared themselves to be, "very big;" and the less ambitious cultivator, who merely grows for the delectation of his lady friends, will often enjoy the satisfaction of being called "a dear man," from the surpassing beauties he will be able to present them with.

Group of Flower Beds, B.

by the way, is A 1 of its colour, especially now that my plants are about three years old. It bloomed profusely and remained so up to the beginning of November, when the plants were taken up and potted off for next year's display. These beds were edged with *Variegated Dandy Geranium*. The horseshoe beds (7, 7), *Stella*, edged with *Arabis variegata*. This design was not so good as I could have wished, owing to my being short of the plants required to fill it as I had arranged. However, it was a blaze of colour, and pleased very many of my visitors.

The opposite geometrical design (B), here drawn to the same scale as the last, is by no means easy to plant, and it will consequently be broken up in a few weeks, and replaced by one which may not look so graceful on paper, but will be much more suitable for the purpose for which it was designed. This was planted as follows: Circular centro bed (1), a specimen plant of *Yucca variegata*, with a broad band of the *Variegated Dactylis*; the triangles (2, 2), *Madame Vaucher Geranium* and *Verbena La Boule de Neige* mixed, edged with *Variegated Geranium Queen of Queens*, the *Verbena* being introduced for the sake of the white bloom, which made up for the "shortcomings"

Walk.

of *Madame*; the triangles (3, 3), *Geranium Flower of Spring*—these beds were very beautiful, and greatly admired; the two boundary V-shaped beds (4, 4), *mixed Verbenas*, edged with *Gnaphalium latatum*; the boundary V-shaped beds (5, 5), *mixed beds of Purple King Verbena, Geranium Manglesii, and Variegated Alyssum*. The arrangement of this design was much more successful than the other; but No. 2 beds were not satisfactory, owing to the indifferent blooming of *Madame Vaucher*.

The border on the right-hand side of the garden was filled with a mixture of *Geraniums, Verbenas, Heliotropes, Tagetes signata pumila, Petunias, Stocks*, and other bedders "on trial," backed by *Dahlias*.

In the centre of the lawn on the left side there stands a very fine specimen of *Arucaria imbricata*, around which the turf has been removed for some distance, in the same manner as those at the Crystal Palace. This space was

Here is another indentation for the rosarian's thoughtful brow: "suckers," a word delightfully suggestive to the juvenile imagination, but equally abhorrent to the mature rosarian mind. Do what we will, these nuisances crop up more or less, like the daughters of the respectable horse-leech, crying ever, "Give, give!" draining the strength of our favourites, turning roses into stocks, betraying growers into unseemly language, and a state of irritation by no means congenial with the gentle spirit which should animate the votaries of floricultural science. How are these pernicious parasites to be eradicated? There is but one way of dealing with the

plague—the careful application of the knife at the time of planting. Every vestige of an incipient eye should be removed; not simply pared smooth with the surrounding surface, but scooped boldly out, like extracting the core of an obnoxious corn.

Again, there is nothing which demands the enthusiastic rosarian's watchful care more than the selection of a skillful workman to plant his trees when he has obtained them; for fine plants are but fine failures if not properly placed in the ground. Let jobbing gardeners, or third or fourth rate nurserymen, who send out men of a similar grade, be eschewed as rosicides. There be some such, as the rosarian of Chaucer's time would have said, who knowe not yo briar from yo mannetio; I wolde not truste soche, I ween, to plante oven a birche brome. Plants will be ruined, temper spoiled, money wasted, if these ignorammuses are trusted. "Horresco referens." I once fell a victim to the proceedings of one of those barbarians. Plants died by the dozen. New and expensive varieties gradually fell into the sear, the yellow-leafed condition, and dwindled away without apparent cause. When the skeletons of the defunct, however, were removed, to be committed to the muck-pit or fire, their disorder was apparent enough. Briars had been planted a foot or more deeper than the collar; manetti works were left three or four inches above the ground. This was a lesson to go to a first-rate nursery only for men to plant roses, and, indeed, also for the plants themselves. "Verbum sap."

Another point in planting roses, not half sufficiently attended to, is the careful expansion of the roots in the ground before filling in, and the completely surrounding their fibres with some soft encouraging loam or comfort for them to run into, and the tender spongiolos to take up when spring growth begins. How can healthy growth, or any growth at all indeed, take place when the roots of plants are jammed together like a Chinese lady's toes, and the delicate young fibres have to make their way into earth trodden as hard as pavement and as sticky as soap?

There are few objects in the garden which exhibit a more disconsolate and forlorn appearance during winter than standard rose-trees; they present, however, a much more dismal aspect tied in bundles at the doors of the London seed-shops, like samples of birch-brooms. I saw my friend Greenhorn the other day labouring to the train under a huge packet of standards, which he had purchased on his way from the office, believing he had secured a treasure at a marvellously low price. The shoots were already shrivelled and yellow, and their roots looked like bundles of withered horse-radish. "What do you think of these, old fellow?" he chuckingly exclaimed, "I rather flatter myself this season I shall take the shine out of even you." I recommended him, in reply, to have the knobbyest and thickest trimmed into walking-sticks for nocturnal purposes during the winter festivities, as they would be sure to be dead in the course of the spring. Elderly ladies too, of confiding dispositions, and old fogies who wish to grow roses on "the cheap," are very fond of purchasing lots at the sales. Such a method of procuring roses is a delusion and a snare. The plants are usually the refuse of small country nurseries, where the stock consists of bygone varieties, and they have commonly, moreover, been out of the ground till dry, knocking about in sheds and railway vans. A rose, to thrive properly, should be out of the ground the shortest possible time, and if sent any distance the roots should be carefully packed in wet moss, well covered in with sound exterior layer of straw. The branches, especially the work should likewise be treated in a similar manner.

"All that's bright must fade," saith some poet or other; and, unfortunately, roses, like poor humanity, are subject to the disagreeable propensity of growing old. More fortunate than we, however, they are capable of being rejuvenated to a certain extent, and this is the process of grinding roses young again. At any time, from November to the end of February, weather being suitable, carefully take up the plants without damaging the roots, and remove a cubic yard of earth from where they have been growing. Fill up the cavity with a mixture of the strongest maiden loam and rich manure; then cut back the roots of the plants considerably, selecting a nice tuft of fibres for the termination of the operation. Demolish every vestige of a tap-root; exterminate even the ghost of a sucker. Cut back every main shoot of the head to within two eyes of the work. Be especially careful that the pruned roses are placed in soft maiden soil only, away from any contact with manure; indeed, this practice should be a canon in all planting.

I will just add two or three little "crowsfeet" nevertheless, not to be despised on that account. Wash your "stocks" as well as your stockings. If you wish to avoid green-fly, import half a peck of ladybirds. If you wish to prevent your

"toas" from catching cold, give them a "nightcap." Lastly, if you are ambitious to become a first-rate rosarian, take in the GARDENER'S MAGAZINE!

W. D. PRIOR.

Clapton.

THE SEASONS AND VEGETATION AT THE ANTIPODES.

In the Proceedings of the Royal Society of Tasmania, occurs a list of the Leafing, Flowering, and Fruiting of a few standard plants in the Royal Society's Gardens, which shows the bearing of some of our garden plants at the Antipodes:—

December 12th, common Privet commencing to flower; 15th, first bunch of Red Currants ripe; 20th, first bunch of Black Currants ripe; 25th, *Mollia Azedarach* commencing to flower; 31st, *Doyenné d'Été* Pear commencing to ripen.

January 10th, *Veronica angustifolia* in full flower; 11th, first ripe Apricot gathered (Royal); 18th, *Groevilla robusta* in full flower; 18th, first Jargonelle Pears gathered; 25th, *Catalpa syringifolia* in flower; 30th, Black Mulberries commencing to ripen.

February 1st, Peaches commencing to ripen (George IV.); 8th, Kerry Pippin Apple commencing to ripen; 11th, Windsor Pear commencing to ripen; 16th, Bon Chrétien Pear commencing to ripen; 16th, Greengage Plum commencing to ripen; 26th, Ash commencing to shed seed.

March 9th, tip of Hornbeam commencing to turn yellow; 10th, *Colchicum autumnale* in full flower; 12th, *Coc's Golden Drop* Plum commencing to ripen; 14th, *Szeckel* Pear commencing to ripen; 15th, tips of Elm turning yellow; 16th, Horse-chestnut leaves turning brown; 20th, Oak-leaves commencing to fall.

April 3rd, Chinese Chrysanthemum commencing to flower; 4th, Elm-leaves commencing to fall; 9th, *Coc's* fine late Red Plum commencing to ripen; 18th, Mountain Ash-leaves commencing to fall; 25th, leaves of Black Mulberry commencing to fall; 30th, seeds of *Carpinus betulus* commencing to fall.

May 10th, first Medlar ripe; 17th, *Coronilla glauca* commencing to flower; 25th, *Ailantus glandulosa* leaves all shed; 30th, *Photinia serrulata* commencing to flower; 31st, *Spiræa prunifolia* commencing to flower.

MONKEYS IN THE COTTON FIELDS.

A cotton planter from Georgia gave his experience, some time ago, in the *Galveston (Texas) News*, on training monkeys for picking cotton. He writes that in 1849 he owned a cotton plantation in Georgia, and that having occasion to visit the Island of Trinidad, he was persuaded to buy twenty-three monkeys, at a round price, to test their latent capacities for cotton picking. The letter adds: "I was mighty well pleased when I received my monkeys. Their arrival turned my plantation topsy-turvy. For two weeks nothing was done by whites or blacks but play with the monkeys. The overseer got one of the brightest looking, and remained at his house most of the time watching the monkey's tricks, and I must confess that my wife, myself, and children were in the same business. Seeing this would not pay, I began making preparations to go to work. I had reckoned on one negro managing ten monkeys, and five monkeys picking as much as three negroes.

"For the next two weeks, all hands, whites and blacks, were engaged in the cotton fields teaching monkeys. The result was somewhat different from my calculations. Instead of one negro managing ten monkeys, &c., it took ten negroes to manage one monkey, and then the monkey did not pick a pound or an ounce of cotton. I became disgusted, gave all my neighbours that would accept a monkey, and about a fortnight since sold the last eight to a travelling menagerie at five dollars apiece. My monkey speculation has thrown me behind six weeks in cotton picking. The next time I go to Trinidad, I don't believe I shall want any monkeys."

A GAY CHIMNEY AND A FRAGRANT GARDEN WALK.—The following directions "To dress up a chimney very fine for the summer-time, as I have done many, and they have liked it very well," is extracted from a curious work, entitled, "The Queen-like Closet, or Rich Cabinet," by Hannah Woolly, 1681: "First, take a packthread, and fasten it even to the inner part of the chimney, so high as that you can see no higher, as you walk up and down the house. You must drive in several nails to hold up all your work; then get good store of old green moss from trees, and melt an equal proportion of beeswax and resin together, and while it is hot dip the wrong ends of the moss in it, and presently clap it upon your packthread, and press it down hard with your hand. You must make haste, else it will cool before you can fasten it, and then it will fall down. Do so all round where the packthread goes, and the next row you must join to that, so that it may seem all in one. Thus do till you have finished it down to the bottom; then take some other kind of moss of a whitish colour and stiff, and of several sorts or kinds, and place that upon the other, here and there, carelessly, and in some places put a good deal, and some a little. Then any kind of fine snail-shells, in which the snails are dead, and little toadstools, which are very old, and look like velvet, or any other thing that was old and pretty. Place it here and there as your fancy serves, and fasten all over with wax and resin. Then for the hearth of your chimney you may lay some orpine sprigs in order all over, and it will grow as it lies. And, according to the season, get what flowers you can, and stick in as if they grew, and a few sprigs of sweet-briar. The flowers you must renew every week, but the moss will last all the summer, the orpine will last near two months." One phrase in the above should particularly recommend it to such of our readers as, in the nice language of the day, have a love of propriety. "Little toadstools, &c., and anything old and pretty." Was ever antiquity so smoothed over? The culinary recipes have nothing remarkable in them. Everything, to the meanest meats, is sipped in claret, steeped in claret, basted with claret, as if claret were as cheap as ditch-water. I remember Bacon recommends opening a turf or two in your garden walks, and pouring into each a bottle of claret, to increase the sense of smelling, being no less grateful than beneficial. We hope the Chancellor of the Exchequer will attend to this in his next reduction of French ~~wines~~, that we may once more water our gardens with right Bordeaux.

A PLEA FOR THE VARIEGATED CURLED BORECOLE.

In your remarks on Winter Decoration of Flower Gardens, contained in the GARDENER'S MAGAZINE of the 7th ult., you write disparagingly of the variegated kale for winter decoration, at same time recommending them as being well adapted for the shrubbery borders and the kitchen garden. We must differ from you so far, as we find them very ornamental in flower-beds or borders, when properly treated. At present we have a bed filled with Melville's triple curled, which looks even at present quite brilliant, and when the plants begin to make a little fresh growth they will then look even more so. The centre of our bed is dark purple, surrounded with three rows of mauve, finishing with an edging of white. Our treatment is as follows: To keep them dwarf and compact, and to bring out the true colours, we sow the beginning of March thinly; after the plants are a moderate size we transplant them into poorish soil, in an open space of ground, but not too close together. They remain there till wanted for use, when they are removed at any time to the winter garden. We plant out in November, and keep the heads with their foliage close to the ground. We cut off all the lower rough leaves, leaving the rich-coloured centre or head, which in all weathers will be found to stand up neat and trim, even in bright frosty weather. Although the plants are much reduced in size by cutting off the under leaves, they can be planted much closer in the beds. Another plea in their favour,—they are within the reach of every one; a packet of seed can be bought for one shilling, enough for most purposes. One plant of a good sort of ivy would cost as much. We agree with all you say in praise of the latter, *i. e.*, the ivy, as being beautiful subjects for winter decoration.

STUART AND MEIN.

Kelso, N.B.

FAIRLOP OAK AND FAIRLOP FAIR.

There is one mystery of mankind that always baffles one, and that is, why it should be necessary for people to go to fairs. If I only knew why, I could begin this paper with a philosophical observation, and show that it was in obedience to a stern and deep necessity of our moral natures that my excellent friend and neighbour, Dr. McDonnell, and myself, were wafted on the wings of a mutual impulse to Fairlop Fair on Saturday last. No; not on the wings of a mutual impulse exactly, for we had the wings of Pegasus to bear us along, and it was the mutual impulse that made us willing to give Pegasus an opportunity for a flight through some miles of London fog, and some more miles of country rain, slush, and chilling wind. I'm so satisfied that no human philosophy can account for the proceeding, that I begin my task by giving it up. What I give up is the mystery, not the task, for it is to tell a story that I have begun with these incoherences. The story should begin with the impulse. We, that is to say, not the humbugging "editorial we," but the Doctor and the Party now inditing, and who no doubt deserves to be indicted for sharing in the impulse and perhaps for its initiation,—we started in our open phaeton with a brisk bay-coloured Pegasus with a flaxen tail for Fairlop Fair, on Saturday last, the 14th of December. All other people who go to Fairlop Fair prefer the first Friday in July, for it is then a rather lively proceeding; or I should say *was*, for Fairlop Fair was finally closed by us on Saturday last, and will be heard of no more except through these immortal pages. Yes, Dr. McDonnell and the Party inditing were the last frequenters of the scene of revelry which for 150 years has on the first Friday in July been enacted in Hainault Forest. I have not known the forest or the fair through all that time, but only since thirty-five years perhaps, having been born some three-and-forty years ago at the London end of the long stream of people that lined the road on Fairlop night, to see the fairing people and the boats returning. We agreed to go and see what was to be seen on a dull sloppy December day; and we did well, for from first to last we had a glorious holiday, and Pegasus was as ready when all was over for another flight as if, when he was stabled steaming and muddy, he had only just started in the freshness of youth from the blood of Medusa. Being a thorough East-ender, it was my part to play pilot, and guide the Fairlop boat. We left Stoke Newington about half-past ten, and steered through Hackney to Old Ford, in order that, for thoroughly enjoying the fair, we should be first ground young. When I was a small East-ender, and, with the rosy hue of smiling youth, ranged on happy foot and light of heart in innocence and glee over Ben Jonson's fields, and with superexcellent innocence caught red-poles in the meadows flanking "Cut-throat Lane" (where is the East London Cemetery now), to sell to schoolmates at "tuppence apiece," there was famed in that happy land a sweet retreat, called "Clay Hall," where the delighted youth of both sexes witnessed for a consideration the gyrations of some painted dolls, which performed the attractive drama of "Decrepit Age transformed to Youth." There never was a grander treat than *that*. Nobody that I knew ever wanted to see anything grander; and nobody ever had seen anything more wonderful, beautiful, and refreshing. So away we went through Victoria Park, and thence down the Old Ford Road, and at last we pulled up at a very commonplace looking "public," finding ourselves at this great landmark, this remaining beacon of the light of other days,—this happy island of the world of innocence and glee that once was, and which still bears the happy designation of "Clay Hall." Pegasus snorted with disdain, to inform us that he was not usually so arrested in his wild career when in the service of Apollo and the Muses; but on being assured that we were seeking the gift of perpetual youth, he stood patient while we sought the necromancer. A mild damsel in the bar received us, and to our trembling interrogations replied that they still ground old people young in the *summer time*. "Then this bold expedition," we expostulated, "must have the blight of a disappointment upon its initiatory phase, and an omen, dark and dreary to presage its dreary end." The damsel was impenetrable, immovable, unpoetic, and renounced her necromantic art; and so we strolled into the garden to behold the spot where, through the aid of the painted dolls, many generations had been delightfully informed of the possibility of second childhood. Oh, the changes that time works! What was to me once upon a time a region of enchantment was now only half an acre of mud. The ground was greasy and sour, the great grass-plot had become a miniature bog, on the farther side of which a dead pavilion seemed to float like a cast-up shanty of the primeval men. This dead pavilion is no doubt the principal retreat for people who still go there in the "summer time," to be reminded of Pygmalion and Frankenstein and Meph., and such other people, who, in common with the keeper of Clay Hall, have the gift of the renewal of youth. I presently descried other dead pavilions of a ghostly washed-out blue

colour starting out from the far-off walls all round, like as if Charon would occasionally row across the bog, and convey a dead doll to the nearest dead-house he could find. How were we startled to meet the Queen hero, standing bolt upright, clad in faded robes of state, and looking fixedly into futurity, guarding one of the dead-houses! But so it was; and her majesty's feet somehow changed into great clumsy acanthus leaves; for the wooden figure carved and painted to represent the mighty and beloved sovereign of these realms, was mounted apparently on some worn-out capital of a disused wooden pillar, and so was saved the ruin of her royal feet from contact with the bog. On the other side of the same dead-house rose a fearful spectre, with the head and shoulders of a man terminating in vast acanthus leaves; it might be a colossal bust of somebody stuck ruthlessly in the mud, but I think it much more likely it was a pale giant immersed to the waist to undergo the earth cure for rheumatism. Filled with fear and dread at these things, we stole about suspiciously, looking for the awful mill where the grinding was performed. All our fear was soon dispelled by laughter, for we found a sort of a little shop, twelve feet or so wide, with an iron railing in front to keep back the crowd (when there was a crowd), and in front of the shop a long shutter; and I remember that when that shutter rose in days gone by, the wondrous work of rejuvenating delighted the eyes of all beholders. It was once so vast, so grand, so wonderful, but *now* it was a very small and very washed-out peep-show. The Doctor immediately plunged into the depths of his erudition, and began to recite Moir's beautiful lines on "Disenchantments," while I called to mind that on one side of the show we used to see an aged pair go tottering to the mill, and presently the same pair came out skipping on the other side all joyously in the flush of youth and love,—and we knew them to be the same by their garments. We quaffed a refreshing bowl, gave Pegasus the signal, and away we went, feeling a little bit the younger for having seen the outside of the show.

At every step, as we paced over ways that I had known from a boy, the many marks of change were almost past belief. All the substantial villas that had ivied porches, and the old gardens that had picturesque gateways, are gone, and in their place are dense blocks and rows of small houses, most of them newish, and all of them humble. No, the porches and gateways are not all gone. We noticed the remains of a grand old garden on the left, the old trees within looking very sooty, and the wall without being quite covered with the gigantic autograph of Griffiths and other varlets in the whitewash line. Next we noticed a fine old Norman-looking gateway, with a scrap of ivy nodding from it, like the one lock of curly hair left on a bald-headed patriarch. This had been the entrance to a fine place, which had now become a wood-yard. We uttered an invocation, "Woodman, spare that arch!" and told Pegasus to go on. Presently we emerged into the high road beside Bow Church, another and a genuine bit of the picturesque which the March of Improvement has left untouched.

We took the road to the left of Stratford church, and then began to feel we were in the country. If you know the route, you will agree that all about the Green, from the front of Stratford church till you reach the railway bridge, is as perfect a picture of an old country town as you can well have, considering there is no market-place, no cross, no cage, and no great butcher's shop with elm-trees in front, and a great penthouse to shelter the rosy meat. Next past Bunney's nursery, and so on to Leytonstone. Now, let me tell you that a drive of this sort on a dull December day is far from unenjoyable to those who really love the country. The well-kept rural boxes of the wealthy Cits present a series of bright pictures; their great yew-trees, great firs, and great cedars; their rich groups of evergreens in the spacious front courts, the rich planting of deciduous trees round about, in the midst of which gigantic oaks, walnuts, and elms, rise up to take a peep at the passers-by; the gleam of the glass-houses, seen over the tips of dark ivy-covered walls; and the invariable lively trill of a song-trush, or the chir-r-r-r-r-r-ah of a startled blackbird,—afford most delightful variations from views over ploughed lands, and the occasional watching of great flights of lazy rooks skimming the highest heavens in search of fresh pastures. We had a little laugh at the little effigy that grins over the doorway of the Red Lion: it is a lion with mouth from ear to ear, and is undoubtedly the very lion from which those ingenious artists to whom we are indebted for lion-mouthed letter-boxes borrow the idea. Bravo, lion! and *esto perpetua*, with any other bits of Latin that may appear appropriate. The Crown next, with its picturesque portico. We ought to have brought the great effigy of the Queen from Clay Hall to present it for this portico. Pegasus refused to stop, so in another instant we passed the Green Man,—the immortal, renowned, romantic Green Man, and then we were actually on the forest. It is not the forest now so much as it is the "Cowley Park Estate." There are some gravel pits and some furze-brakes, and some clumps of trees, but the forest is gone, gone, gone; and I shall never sing away the sunny days in its leafy glades, or dream of Robin Hood amongst its giant oaks, or gather blackberries in the mellow autumn there again. No, nor will any of the East-end boys, for the glades are cart-roads, and the oaks have become timbers or firewood, and the blackberries are trampled in the dust. Towards Woodford there is much lovely forest still, and from thence to Buckhurst Hill and onward glorious scenes remain; but they are all doomed, doomed; the builder and the farmer are dividing them, and Utility is putting Poetry under its iron heel, to blot it out for ever.

But our way is really towards Hainault, and a pretty long round we are making of it. We pass Wanstead village—charming spot even on this dull winter day—and so on, through charming country, rising in swelling uplands crowned with fur-parted clumps of trees, and we are not long in reaching Barking-side. Don't confound this with the river-side Barking; for that is miles away to the south-east. On the left we note a little ploughman's public, called the "Old Fairlop Oak," and presently we enter by way of a good new road through a sort of sea. Now observe, I speak of this place as like a sea, for on either hand stretch wide and far immense billowy-looking corn-lands, and it is now raining fast, and the brown clay glistens, and the thin crop of weeds contributes a greenish shining gleam to the vast landscape, so that it looks more like water than land. There is on the left a well-compacted farm of quite the modern school, and we say, "Here dwells another Mechi." Neat labourers' cottages, neat galvanized iron straw-sheds, endless rows of corn-ricks, and innumerable flights of small birds that rise in clouds, and circle and mingle and wheel about, mostly going on before us as if to clear the way; and labourers visible at distances, though the work is almost stopped by the rain, and the half-finished furrow tells of the activities that only the unkind elements could check. Masses of trees on the horizon, and clumps of trees as on low islands rising from the general sea; but otherwise the aspect of the place is that of a thoroughly settled, farming country, where there has been no forest for at least a thousand years. Now for the "Disenchantment," which the Doctor would recite again, but

he begins to feel the cold as I do, and is, like me, smitten with the pangs of hunger, and Pegasus is a most black with wet and goes along in a cloud of his own perspiration. The farm belongs to Mr. Ellison; and in the great corn-lands on the right of the road as we go forward is the site of the once-famed Fairlop Oak and Fairlop Fair. The oak has gone long ago; the fair was held for the last time in July 1867; and, according to the best known maps, we are now in the very heart of HAINAULT FOREST.

On again through the blinding rain and through a sea of mud, that Pegasus plunges at, and that is a more serious sea for him than the drenched corn-lands are to us. Presently we see burst from the billows, like the enchantment of the Fata morgana, the charming village of Chigwell—name renowned in story, name precious to all East-enders who love the old forest, and remember something of its departed glories. Yes, we are within hail of Chigwell Row, and the muddy glimmer of the well-known pond warns us which way to steer through the rain and murk, and in another three minutes we are within the shelter of the brave old Maypole Inn, which for 200 years has received the weary traveller, and made him forget the cold, the danger, and the fatigue of forest travel in far worse weather than such mild drenchings as ours of to-day. I quite expected to see the ghost of Hugh (you remember him, of course—Maypole Hugh!) come forth to take charge of Pegasus; but another Hugh, whose Christian name is John, was there instead, and we saw the winged steed eating vulgar corn, and being kindly rubbed down and covered up by the other Hugh, ere we put our feet before the blazing Maypole fire and prepared for dinner.

We began by tasting the Maypole ale by the same hearthstone at which Mr. Dickens warmed his toes when exploring these parts, to give the strong touch of picturesque reality, the true breathings of the forest and its grim traditions, to his glorious story of "Barnaby Rudge." Mrs. Maypole remembered Mr. Dickens and all about his visit. The house and its surroundings were sketched for those charming pictures from the pencil of Hablot K. Brown with which the life-like tale was embellished when it first appeared. If Mr. Dickens had as good a steak, with as piquant gravy, and as snowy foamy potatoes, and as good ale, and as cheery a bottle of old port, as fell to our lot, he can have no quarrel with the Maypole; he must, indeed, love it for its own sake, to say nothing of its picturesque power in the principal scenes of that best amongst his many wondrous works. We did not pick up a single tradition of him, for it was not our business to be inquisitive in any such matter; but to gather up all we could of Fairlop and Fairlop Oak. But we did sit by the bright wood fire sipping the good wine, and talking of poor daft Barnaby, and the matchless skill with which this most original character is developed. And we went over all the plot, for it seemed as fresh to us as if we had read the tale but yesterday, though neither of us had seen a page of it since it first came forth, a surprise and a delight, some five-and-twenty years ago. Oh, the "pleasures of memory"! to have all that story fresh before us, like a drama acted in the bright wood fire. There we saw the cold-hearted Chester confronted by the implacable Haredale, and John Willet and the gaping tipplers listening to hear the due fought in the great room above, and remembered their comical disappointment, and the dreadful hate that on both sides stayed its expressions in blood. Old Varden, too, and the wounded Edward, and the lovely Dolly Varden, and Simon Tappertit, and Miggs,—O Miggs, Miggs!—and the incomparable fainting fit, when Simon stuck her against the wall, and left her like a broom that had been crossed in love. Just as we got to this part, the fire fell in and showered a lot of sparks on the hearth, and instantly we had a great picture of the burning of the Warren, and could hear the dreadful bell, and saw the direful Rudge; and through all the scene rushed the mad Hugh upon the stalwart steed, and London itself fed the flickering flame; and that madman Lord George Gordon fed his vanity and his fanaticism on the wretches that lay down in the Holborn gutter, and drank from the stream that the burning distillery supplied, and rose up maddened, and rushed to their ruin. The fire fell in again, and we saw Joe Willet married to the lovely Dolly, and were shocked to hear the Raven Grip cry "Amen;" and at that instant Mrs. Maypole appeared with pipes and tobacco, and once more we suffered a disenchantment, and came back to hard reality and demonstrative prose.

While we saw Pegasus harnessed again for his mean drudgery, and though the minister of Apollo still willing to be useful to mankind, we looked about in the dusk for a few of the old landmarks. "Ah," said the ostler, "I've stood here and counted the deer." No doubt; but in his time, as in ours, there were never many to count, though there are a few somewhere, and one especially that is kept for the Easter hunt, and that every year still makes his run from Fair Mead bottom whither he likes, but always where none but a certain gifted few can follow him. I can remember, too, when all round about here, for miles and miles, the forest gave its pleasant shade to millions of violets and primroses on cushions of greenest moss. Then it was that Fairlop was in its glory. Every year, on the first Friday of July, the East-enders poured forth in crowds, and the worshipful Society of Blockmakers, the descendants, in the mechanical line, of Daniel Day, the founder of the fair, led the way in well-built and very gaily painted boats mounted on wheels, with smart teams and postilions, with streamers, trumpets, and loud huzzas. Until the boats had appeared, the traffic of the road was as nothing compared to what followed; and at the forest until the boats came upon the scene the fun of the fair had not begun. Their appearance was the signal for anything and everything. Gongs were sounded to call the attention of the admirers of fat women and male giants, numbers of such being on view; brass bands threatened to split the heavens and shatter the trees with blasts of terrible melody, because there was a tragedy to be acted in five minutes; or Mr. Wombwell (then a reality, and sometime a resident near the canal in the Commercial Road) was ready to admit visitors to see the Polar bear, and the lioness that had a litter of whelps. Then the booths were opened, and the drinking and dancing began; then, for three throws a penny, there was a chance of getting a useless pocket-knife, if you could but hit it, and for the paltry sum of "two-pence you might swing sky-high, and nothing extra to pay for being sick." How many commonly went to the fair, think you? Well, a statistical postman, whom I met at Stratford not long since, told me he had counted 4,000 vehicles of various kinds going down the road on Fairlop day, and that passed by one spot in the space of four hours. Many a one-horse trap would contain sixteen persons, "all agog to ride through thick and thin;" but the average all round would be eight to every machine, a total of 32,000; so we shall not be far wrong in estimating that the visitors to the fair averaged 50,000, even in its latter days.

At night the Mile-end Road used to be just the counterpart of the Kennington Road on the Derby day; but the scene had this peculiar characteristic, that every carriage, cart, drag, dray, or what else, was completely covered with green boughs, so that one might say Birnam Wood had come to

Dunstable. It is a matter worth noting that on the first Friday of July, every year, the forest was torn to pieces; the people went to enjoy and also to destroy. We must remember such points as these when in the humour to howl about the decline of old customs. The best I know about the night was what used to take place at the "King's Arms Assembly Rooms," at the corner of Beaumont Square. The great Hemingway (he was great to his boys then because of his public duties) was living then, and it was the custom for the boats to halt there, in the midst of an awful crowd, and presently Hemingway used to appear at a window, and bawl out a Fairlop song, having for its burden, which the crowd took up and made a thundering chorus of,

"A charter we've got to support the old spot,
And Fairlop shall flourish again and again."

Once upon a time, I had a fit for collecting materials towards a history of old trees. Poring over a heap of prints at a little shop in St. Martin's Lane, a thrill of delight shot through me on discovering a Catnachian edition of that very song, and another, which used to be sung by Mr. Lidard (Lidard no doubt), both embellished with a most racy woodcut, as primitive as one of Caxton's, and professing to be engraved on a block cut from the original tree. I published a copy of this song, with some particulars of the tree, in "Notes and Queries," of May 15, 1852, and now, in December, 1867, I present the readers of the Magazine with a fac-simile of the sheet (see next page); and if any one likes to have the original for a five-pound note, I will part with it, and pay over the cash to one of our Stoke Newington charities.

The Catnachian sheet will inform the reader that Fairlop Fair was founded by one Daniel Day, blockmaker, of Wapping, about the year 1720. It began as a simple bean-feast to his men, and they selected for their rendezvous a grand old oak-tree that spread over a space of ground 30 feet in circumference; just about the same size, in fact, as the cedar-tree in Abney Park before age and storm had begun to destroy its fair proportions.*

When in its glory, Fairlop Oak had a grand fluted column, which measured at a yard from the ground 36 feet in circumference; its head was formed of eleven vast arms, which rose more in the manner of a beech than in that of an oak. The area of 300 feet circuit which it covered was the original dining place of Daniel Day's party, and therefore became ultimately the centre of the fair. It was barbarously mutilated—the boughs were torn down, the trunk was hacked and hollowed, and fires were lighted in it. At last, a desperate effort was made to save its life. It was enclosed with a palisade five feet high, and Forsyth's composition (then considered a certain regenerator) was applied to its wounds, and a board was affixed bearing this inscription:—

All good Foresters are requested not
to hurt this old tree, a Plaister having
been lately applied to its wounds.

But the lovers of forest fun would persist in destroying it. The palisade was broken down, fires were again lighted within the trunk of the tree, and in the month of June, 1805, it was set on fire, and continued burning until the following day, and was then nearly destroyed. Still it lingered on, a ghostly shell of its former self, a grim reproach to wantonness, a memento for a time of that destructiveness which has ever been a characteristic of the Englishman enjoying himself; but the end was near. In February, 1820 a fearful storm raged in Hainault Forest, and the decrepit tree came down with a dreadful crash, and strewed the ground with its mossy branches and the fragments of its wasted trunk. Nature's silent work through more than a thousand years (for scarcely less than that was its age) was thus mocked by man in his pretended devotion to her beauties and beneficence. What became of the mass none can tell, yet it was not wholly lost; for from the best timber that could be selected from the remains was constructed the

PULPIT OF ST. PANCRAS CHURCH,

which all true lovers of sylvan lore may see by attending Divine service there; and may it do them good to note the splendid carving, and to hear whatever lessons of love and duty are offered them from that venerable rostrum!

It only remains to add that the enclosing of the forest lands has rendered the extinction of the fair inevitable. For some years past it has been permitted within the enclosures, but the permission ended in the holding of the fair in July last, and we may say it has ceased to be. The terms of Daniel Day's will require it to be held in Dagenham parish, and in Dagenham parish no available spot can be found, for wherever there is a suitable place it is on Crown lands, and the Government are resolved to give it a quietus. "Ah," said one whom we questioned about it, "the clergy glory in putting a stop to the people's recreations! It's a good thing they haven't everything in their hands." Well, there are two sides to every question. None who have any sympathy with the toiling masses can resist a strong feeling of regret at the rapid destruction of forests, and the enclosure of picturesque wastes near the great metropolis; but the population increases, and corn-lands do more for mankind than forests; and though a great fair affords a great holiday, and gives innocent delight to thousands, there has been some degree of riot and dissipation mixed up with Fairlop Fair from the very beginning; and we need not look upon the clergy as the enemies of mankind if they desire to purge their parishes of scenes and people that in any degree tend to demoralize their flocks. There may be a way out of all these difficulties—a way of combining all that is jovial, free, and hearty, with absolute innocence of mind and the benefit of health, but we fail to see it just yet, and must wait and hope for a brighter future.

When we left the Maypole it was growing dark. We had to feel our way as it were along the roads, and we took the nearest cut, making for Lea Bridge Road, and we went home in at least half the time we spent in getting there. The day ended pleasantly, as it began. All the way home the rain poured down, but we sat close under the hood, with good wraps about us; and it seemed little else than a flight through the air, that ended in our sitting again before a bright fire, and while drinking good tea recounting our adventures in much the same way as I have done them here. Henceforth, it is only in our memories that "Fairlop shall flourish again and again."

S. H.

* Those who are curious about minute particulars may refer for them to a pamphlet published in 1813, entitled, "Origin, History, and Rise of Fairlop Fair." In 1795 a pamphlet on the subject was published; the title of this I cannot give. In "Excursions through Essex," published by Longman, 1818, vol. ii., p. 56, are some particulars of the tree. In the "Mirror," one of the best of the early-founded cheap and useful magazines, vol. ii., p. 81, is a figure of the tree. In a work published in 1847, entitled "Fairlop and its Founder; or Facts and Fun for Forest Frolickers, &c., printed at Charles Clarke's Private Press, Tobham," are fuller particulars than in any other work. In Mr. Gilpin's "Forest Scenery," the tree is described as one of the finest oaks in England. Lastly, to end this note of the bibliography of the subject, there is a figure of a tree in the "Gentleman's Magazine" for July 1806. None gives no particulars, and that is a marvel!

An original Drawing by an eminent Artist mounted on a Woodcut engraved on a Block of the Celebrated Tree.

The Stem of this vegetable Prodigy, which was rough and fluted, measured, at 3 feet from the ground, about 36 feet in girth, and the boughs extended about 200 feet in circumference. The Fair which is held upon this spot was founded, about the year 1720, by Mr. Daniel Day, Block Maker, of Wapping who gave his men an annual Bean Feast, under the shade of the Oak, on the first Friday in July, and which has been visited for a number of years by the Block Makers and Watermen of the eastern part of the metropolis, who parade round the spot singing the following Songs.

Song from the Block Makers' Boat, sung by

Mr. HEMINGWAY.

George, our great King as he sat on the throne,
The supporters of Fairlop sent in their petition,
That he the old Oak in true wisdom would own;
The answer returned from the head of the Nation—
This we agree, that the Maggot and Spot
Never shall be crushed, but for ever shall reign;
A Charter we have got to support the old Spot,
And Fairlop shall flourish again & again.
This answer so noble abroad quickly spread,
The enemy to friendship began to complain,
That this Fair of mischief was surely the head,
And if suffered would certainly soon show its aim,
Down cried he with this Fairlop Tree;
But George, ever generous, said, Cease to complain. A Charter we got, &c. &c.
Freedom, the Goddess for Britons so fair,
When she heard that a few of her supporters so free
Did reverence the Oak which was always her care,
And she said that the day ever sacred should be,
The Maggot and Spot the care of us shall be,
And never shall be crushed, but for ever shall reign. A Charter we got, &c.
Bright July now comes on, when we all are so gay;
The first Friday in the month we all know,
Our Maggot for ages shall shine on that day,

And every year some new splendour shall show.

When we agree that the Maggot and Spot
Never shall be crushed, but for ever shall reign. A Charter we got, &c.

Now my brave boys, since united we be,
With friendship and harmony keep up the day,
Our boat rigg'd and mann'd well, so pleasant to see,
There's nothing can equal our Maggot so gay.

A Toast now I say to good Daniel Day,
Who taught us first this Fair to maintain.
A Charter we have got, &c. &c.

*Written and Sung by Mr. Lidard,
from the Watermen's Boat.*

Come to Fairlop Fair, my good fellows invite

To partake of that day, that is our delight,
For we have spirits like fire, our courage is good,
And we meet with the best of respect on the road;

Would you see us you'd say, when we are muster'd quite gay,
Success to the lads that delight in that day.
Haste away, haste away, all nature seems gay,
Let's drink to the joys of Fairlop so gay.

Our horses are all of the very best blood,
Our boat is well built, and her rigging is good,

With our coats and our badges we unanimous agree,
And join hand in hand to support the old Tree;

There's old Cruff and young Cruff our music shall play,
While George Hall's staunch ponies shall tow us away. Haste away, &c.

'Twas one Daniel Day that invented this fair,
As hearty a fellow as ever was there,
The lord of the manor our Charter did gain,
And we sons of old Neptune will uphold the same;

We'll enjoy all the pleasure that springs from the day.
And ever remember that old Daniel Day.
Haste away, &c.

From Wapping Old Stairs away then we drive,

Upon the first Friday that comes in July;
We breakfast at Woodford, at Loughton we lunch,

And return back to Roundens to dine and drink punch;
Then our boatswain he starts us away to the Fair,

While Phoebus does shine on our colours so clear.
Haste away, &c.

It's when from the forest to Ilford we steer,
Every town we go through we'll give them three cheers;

Then up to Tommy Wright's for to get refreshed there,
Then return back to Wapping to sup of the best fare;

Where we'll dance and sing so cheerful and gay,
And ever remember that old Daniel Day.

Now, having described our boat, horses, and crew,
And our Fairlop so gay, which you all do review,

Our boat she comes home by the winding of eaul,
And now you are welcome into Fairlop Hall;

Our boat we'll put up for another fair day,
And ever remember that old Daniel Day.
Haste away, &c.

A few years before Mr. Day died, his favourite oak lost a limb, out of which he procured a coffin to be made for his own interment, and often used to lie down in it to try how it would fit him. He died Oct. 13, 1767, aged 84, and his remains were conveyed to Barking by water, pursuant of his own request, accompanied by six Journeymen Block and Pump Makers, to each of whom he bequeathed a new leathern apron and a guinea.

WINTER WREATHS AND BOUQUETS OF DRIED EVERLASTING FLOWERS AND GRASSES.

Before naming the lists of flowers and grasses employed in the formation of the bouquets and wreaths which you desired I should send you, I wish to make a few remarks. Some experiments were made here last winter with ferns, but all proved miserable failures. Perhaps you know of some good way of preserving these things; if you do, pray let out your secret. What I have seen of sand-dried ferns and flowers have not prepossessed me in their favour. When I see a bouquet formed with these combined with dyed flowers and grass, I turn sick at heart at their untidy, tawdry, and unnatural appearance. It is against the advance of taste to encourage and use such material for the purposes of decoration. As taste is of the first consideration in this sort of work, let us disqualify such got-up things, and consign them to the rubbish heap, their fittest place. You must be well aware how seldom flowers are tastefully arranged. Fresh flowers share this want above others. Your frequent visits to shows and elsewhere must convince you of this. The bouquet that struck your fancy most during the past season was exhibited at Nottingham, I think—described in your Magazine as being composed of pink, white, and blue flowers—and a confirmation of this. By the by, you did not make known the names of the flowers used in it. You must be familiar with the flowers and varieties of grass as used here in the formation of the bouquets and wreaths, and perhaps in your time have treated them as pets, as I do now. Do not therefore expect me to trouble you with a treatise on the best mode of cultivating these things, most of which are as simply managed as the grass in the fields, as well as the subject being well-nigh written out. There are a few exceptions of course in an extensive list. If all went on smoothly in the art of cultivation, much of its pleasure would be gone, and I fear with it much of our energy. Some plants may be bad to manage and grow, with the best attention bestowed upon them; but with proper treatment the few exceptions to this list may be brought to flourish in a most satisfactory manner.

All the plants having arrived at the flowering state, a sharp watch must be kept over them, to secure the fresh young blooms; picking them when dry, laying them on papers on shelves, in an airy warm place, where they may be quickly dried, so as to store them away, to make room for others. When a sufficient variety is dried, they can be made use of at once. A little time and experience will soon teach the unpractised the correct moment when to pluck the flowers. For variety, they must be gathered at various ages, from the coloured bud to the wide expanded flower. The storing place should be very dry, damp and moth being their greatest enemies. All the flowers might be immersed in a solution of corrosive sublimate and spirits of wine, which would keep them free from the depredation of the moth. Perhaps few would value them so much as to take such trouble in their preservation. However well cared for, the brightness of the colours will fade in time, so that when last year's flowers are placed near this year's gatherings, you would pronounce them dull—perhaps I ought to say worthless. The yellows are an exception. In these

faded flowers I see an advantage, as it will keep the cultivator and arranger in annual employment. Little more remains for me to add before I proceed to enumerate the list, except that should the cultivator meet with disappointment the first season do not let that cast him down. None become adepts at once. Experience and frequent practice alone can make him perfect. This will apply equally to the arranger, who must go on enthusiastically in her work of taste until arrived at the goal of perfection. Should the arrangement of what you have seen of these things infuse in you a fresh love for them, and the notice of them in our Magazine gain for them more cultivators and tasteful decorators, it will please me much, for I have no other end in view than to call attention to the usefulness of these beautiful flowers and varieties of grasses for ornamentation.

To the list of flowers I am going to name should be added the *Aphelaxis*, *Gompholobium*, and *Statice*. Firstly, I will call attention to the pretty little white *Ammobium alatum*, which is perennial; not yet killed by a frost of 8° or 9°. Judging by its present appearance, it will succumb to the rude northern influence before April. The *Aeroclinum roseum*, with its lovely tint of rose-pink, is a gay addition. The white variety is also a great beauty, but is scarce. My packet of seeds only produced one plant with white flowers, the others having flowers shading from rose-pink on the outer petals to pinky white on the inner ones. This is in every way a charming annual, and of the easiest cultivation.

Helipterum Sandfordii and *corymbiflorum* produce pretty little clusters of flowers, the first yellow in colour, and the second white star-like ones. These require care in growing.

Polycolymna Stuartii has a curious flower, is a free grower, and is not yet killed by the frost.

Then come the pretty *Rhodanthes*, which will well repay any extra care they may require in their cultivation.

All the *Waitzias* have so far mastered my skill; though I have flowered some of them in the open border this summer, the result was most unsatisfactory. I shall try them once more, some in the border and others under glass.

Now I come to the *Helichrysums*. On these must the decorator mainly depend, which with the above will make up a pleasing variety. My chief stock of these plants was raised from a German packet of seeds of 12 varieties. From the Messrs. Henderson, of Wellington Road, I had

one, under the name of *Atrosanguineum nanum*, which produced very richly coloured flowers; and another called *Borusoram Rex*, yielding fine double white flowers.

The *Xeranthemums* I exclude, though their flowers are so handsome on the plant; in colours, from rosy purple, through various shades, and carnation striped, to plain white. When plucked and dried, the colours fade and look dull.

The list of varieties of grasses is much longer; to make it brief, I will mark what I most fancy with an asterisk (*). **Avena sterilis*, **Agrostis nebulosa*, *A. plumosa*, **A. pulchella*, remarkably pretty; **Bromus briziformis*, *Chloris radiata*, *Chloropsis Blanchardiana*. **Briza maxima*, *gracilis*, and *minor*. **Ceratachloa pendula*, large imposing spike. This has more the appearance of a fodder grass than any novelty I have seen. It is fresh, succulent, and growing with me at this cold time. All around the mother plants spring up young

ones from the fallen seeds. *Chloris barbata*, **Eragrostis elegans*, **Hordeum jubatum*, *Dactyloctenium Aegyptium*, **Elymus glauca*, **Lagurus ovatus*, **Leptochloa Schimperiana*, *Monochytron roseum*, *Panicum sulcatum*, **Paspalum stoloniferum*, **Pennisetum longistylum*, **Stipa elegantissima*, *Lappago racemosa*, **Milium multiflorum*, *Panicum compressum*, **P. jumentorum*, *Setaria macroseta*, and last, but not least, the pampas (*Gynerium argenteum*). Such plumes as we have here of this fine grass compel me to rank it first and foremost amongst large decorators. From six to twelve spikes placed, as if growing, in a large pot, with some of the leaves stuck in with them, is an imposing ornament in any suitable position. Out of a list of thirty wild species of grass I have collected, I will just name the cream: *Phleum pratense*, *Milium effusum*, *Agrostis spica venti*, *Aira caespitosa*, *Arrhenatherum avenaceum*, *Avena flavescens*, *Melica uniflora*, a lovely thing; *Glyceria fluitans*, *Festuca gigantea*, *Bromus asper* and *sterilis*, *Juncus lampocarpus*, *Carex remota*, *C. pendula*, *C. sylvatica*, and the varieties of the cultivated oat.

My seeds I had principally from Messrs. Carter and Co., some from Messrs. E. G. Henderson and Son, Wellington Road, and others from Mr. Thompson, of Ipswich.

Paignton.

VIVIAN OSWALD WALMESLEY.

[We should regret the necessity of adding a word to the above were it not absolutely necessary. Mr. Walmesley sent a bouquet and two wreaths of dried flowers and grasses, and asked for an opinion upon them. We frankly offered an opinion, and at the same time we wrote and asked him for some account of the plants, and the methods employed by him. The result is what we now have the pleasure to make public, the best essay ever written on this interesting subject. As to the examples sent us, the fruits of Mrs. Walmesley's skill, they surpass everything else of the kind we are accustomed to, as much as the sunshine surpasses the noisome flicker of a grease-pot at a country fair. We have seen some thousands of bouquets of everlasting lately, and what were they? Mere bundles of badly dried flowers tied up with dyed moss and dyed grasses, hideous mockeries of the beauty of the natural flowers, grasses, and mosses we have in the work of our esteemed friend. We have placed the two wreaths and a small bouquet in one of Naylor's épergnes, and the annexed figure affords a fair representation of the furnishing; but Mr. Damman, usually so truthful and elegant, has this time rather missed the mark, and given a hard wiry appearance to objects which are really most light, flexible, and elegant. The large bouquet has been mounted in one of Claudet and Houghton's hyacinth glasses (blue and white), and covered with a glass shade, and the result is a most elegant sideboard ornament. As our friend is still desirous of suggestions, we will remark on the subject of ferns, that if gathered when full grown and perfect, and quickly dried between blotting-paper under pressure, they keep their colour and character admirably. The heaths would scarcely need pressing. But we are much more anxious to learn of Mr. Walmesley, and feel that attempting to advise in this case is little else than vanity. Remembering the bouquet alluded to, it was shown, not at Nottingham, but at Peterborough, by Mr. Macaulay, of the medical profession, and consisted chiefly of geraniums, with a few scraps of lobelia. It was of course made by that gentleman's better half. It would be a pity if we forgot to add that all the flowers in Mrs. Walmesley's work are mounted on wires.—ED.]

A BUNCH OF BREVITIES.

A CAUTION TO THE PURCHASERS OF NEW PLANTS.—*A Perplexed One*: It is no difficult matter to me to solve the mystery of the plants in your houses getting infested with all kinds of injurious insects, such as the mealy-bug, red-spider, and thrip, as well as the white and brown scale, since, as you say, early in the summer of this year you bought in many new plants for the decoration of the stove, the greenhouse, and conservatory. It is quite clear that, if any or all of the above-named insects were unknown in your houses before, when you bought the plants you also (unknowingly) bought these very troublesome enemies. But, since you are not the only sufferer in this way, I would wish to make my reply to your letter a general warning to all intending purchasers of new plants, because they are very often the means through which many of the plagues of the garden are communicated from one place to another. It is therefore necessary to have a vigilant eye upon all new introductions before they are placed amongst any valuable collection of plants. They should be thoroughly examined and, if necessary, properly cleansed as soon as they come to hand, before there is any chance of their communicating to other plants anything with which they may be infested. I could name a certain nursery, not twenty miles from London, at which you have only to buy a few azaleas, and you will have thrip in abundance; and if you are a stranger to mealy-bug, just choose a few stove plants, and you will be certain to become familiar with it soon after you get the plants home. The same remarks will apply to the white and brown scales, especially if you purchase a few rather old plants of camellias and acacias.

SOLOMON'S SEAL.—*George Holmes*: I think it is not generally known that this hardy herbaceous plant forces well. I find it a most useful subject for forcing to intermix with other forced plants, and it is really very easy to do. If potted at once, and placed in a cold house for a fortnight, it may be started in a temperature of about 55° until it opens its first flowers, when it should be transferred to the conservatory. The refreshing green of its leaves is a delightful change amongst the more sombre tints of other plants.

THE AER NEGUNDO VARIEGATA AS A POT PLANT.—*P. & Co.*: We have grown this for several years in pots, and find it a highly decorative plant. Its foliage affords such a lovely contrast, when intermixed amongst early cinerarias and such plants as camellias and azaleas. But with us the most telling effect it has made was when a few plants were forced on and placed amongst a selection of forced roses; it was then most effective. Like most other plants, it forces best when established in pots at least one year before. They look best on stems about two feet high, with the strong growth pinched back once in the early summer to form a better head.

EARLY SPRING RADISHES.—*Amateur*: To have radishes out of doors early in the spring, they must be sown on the first mild day after Christmas.

Choose a rich warm spot on a south border. Lay it up high and dry, seeing that it has been previously well dug; rake the surface even, and then sow the seed, and cover it with half an inch of dry soil; failing this, some sifted cinder-ashes will answer; then get some long dry litter from the stable, and cover up the bed with a thickness of about two inches. This must be carefully raked off on one side or end of the bed every warm sunny day. As soon as the seedlings show themselves, reduce the thickness of the litter, except in frosty weather. It is advisable sometimes to change the litter by getting some more lighter and drier stuff. Look out for slugs and birds, and if the plants get drawn by being covered up, shake over them some fine earth or dry ashes. With this treatment I get radishes sometimes, in mild seasons, in the middle of March.

PLANTS WHICH LOOK WELL BY GASLIGHT.—*Kate*: The following is a short list, which may be useful to all who embellish their apartments with plants in flower: Red and white Primulas, Euphorbia Jacquiniflora, Poinsettia pulcherrima, Solanum capsicastrum, Begonia fuchsoides, and a white-flowered Begonia, more erect in habit, the name of which is nivea; to these may be added scarlet Geraniums, also Geranium Madame Vaucher. Variegated-leaved Geraniums are also very showy, while well-coloured leaves of Mrs. Pollock are quite fiery under a brilliant light. All these and many more are adapted for indoor decoration at this Christmas time, but none are more effective than clear whites and brilliant scarlets. No half-tints or misty shades of colour look well by gaslight, and the most showy yellow presents a dirty kind of white. It should therefore not be used by gaslight. Also red and white Camellias.

THE WEATHER IN THE WEST OF ENGLAND.—October was an exceedingly wet month, and when it was not actually raining we were enveloped in a thick fog, which hung about on the tops of the hills for days together. November was, perhaps, the finest in the memory of the present generation, although not the warmest, for, indeed, it was a cold month. We had rain on two continuous days only throughout the month. It was, in fact, a splendid season for the wheat-sowing and all outdoor work. December had no sooner made its advent than the whole garb of nature was changed. Sharp frost and biting north winds of great fury have, up to the moment of writing, continued with but little intermission, accompanied with hail, sleet, and snow. In all my experience I never remember seeing such subjects as broccoli and celery cut up with so little frost, for we have only registered 10° of frost as yet. I have known it to amount to 20°, and the above-named subjects not look worse than they do now. This shows the importance of shelter from the north.

J. C. CLARKE.

NOTES FOR THE KITCHEN GARDEN.—No. I.

EARLY RADISHES.

What constitutes a good gardener? This is a query the solving of which is not beset with difficulty, although the signification may be practically interpreted in various ways. It is to be regretted that many of us form an opinion of our professional brethren by the circumstances which influence our own practice. My humble opinion of a good gardener, apart from other considerations, is he who makes the most of the resources at his disposal, and thus at all times endeavours by perseverance and industry to gratify his employer's reasonable wishes. In regard to the practice of horticulture, we must not be unmindful that gardening tastes vary as much as our fashions. Some may derive no pleasure except in the culture of the most expensive plants, and so value them as the lady does her jewels, not for their utility, but for their costliness; while others may derive profitable and even delightful pleasure in watching the growth of the commoner produce of the vegetable kingdom. Thus far do our required qualifications range in the discharge of our duties to our respected employers. With this I introduce a very simple but important subject to those with whom economy and the securing of a crop are considerations. I shall entitle it Paper No. I. on Kitchen Garden Crops, as it is my intention to continue the subject at intervals. My first steps in gardening, ere I entered on my teens, were commenced in a market garden of some fourteen acres in extent, and I yet retain vivid impressions of the lessons I then learnt; and they have been in after years of great assistance to me. Everything in a well-regulated market garden is done methodically, because with them it is a matter of £ s. d., not of whims or experiment.

Now the most of us that reside in the vicinity of large towns have observed very early in the spring the great quantity of radishes offered for sale, not only in the shop windows, but on the costermongers' stalls, they being the produce of outdoor crops. This happens very often at a period when the supply in a private garden is limited to those grown in a frame. I will just detail the method pursued in the market garden in which I was employed for affording this early supply. There was a plot of ground to which in succession the following crops were allotted. In the month of May, long ridges or trenches would be dug out of sufficient width and depth, allowing a vacant space of six feet or more to intervene parallel with each ridge. The said trenches would be filled with hot manure, and then covered with earth, and at regular distances from each other cucumber plants would be planted, the same being protected by hand or bell glass which had been previously used for the protection of cauliflower plants during the winter. As soon as the cucumbers had ceased to bear, the ground would be cleared, and under each hand-light would be planted as many cauliflower plants as would be desirable. The intervening space of six feet or more would in the latter part of November, or beginning of December, be thoroughly dug and sown with Scarlet Short-top radishes. They would then be covered with short straw or litter which was shaken from the stable manure at various times, and which had been thus collected during the summer months, and stacked in some out-of-the-way spot. When the radishes had commenced vegetating, the litter was drawn off them with a wooden rake on all fine days, but they were covered again in the evening, unless the weather was very favourable. But until the young seedlings were sufficiently strong to resist the depredation of the birds they were carefully guarded by a boy during the day. These radishes would be fit to draw for sale by the first or second week in April, so that the ground would be cleared of the radish crops early in May. Then, again, straight along the centre of the same ground, the trenches would be dug out for the reception of the hot dung, on which the ridge cucumber would be planted; and thus the changing of the crops would be continued from year to year, the cauliflowers and radishes being benefited by the manure used for the cucumbers.

Having said thus much of what I have observed on the cultivation of early radishes in the market garden, I shall now detail the mode as in after years practised by me in private establishments, where it was essential that I should utilize space. Perhaps, as the use of litter as a covering may not appear

tidy or pleasing to the persons visiting the garden, it is necessary for the sake of order that the spot selected for the early crop should be in the least frequented part of the garden. Of course the benefits derived from sun, light, and air must also have our consideration. A southern aspect is desirable. Having made choice of the ground, I dig in plenty of decayed manure. The finer and lighter the soil is for these kinds of crop, the better they thrive, as under any system of culture they always require plenty of water at the period of swelling. If there is an absence of rain after the ground is dug, I subdivide it into beds four feet wide, with alleys of sufficient width to retain the litter when the beds are uncovered. Of course the number of beds must be regulated according to the demands of the family; but for all ordinary requirements, three beds of four feet wide and twelve feet in length will suffice. About the last week in December I sow the following varieties of radishes, viz., *Scarlet Short-top Red* and *White Turnip*. With the short top I would thinly scatter some seed of the *Early Horn Carrot*, which would succeed the radishes for use. Previous to sowing the red and white varieties, the beds should be planted with some favourite dwarf variety of the ash-leaf kidney potato, not more than one foot apart. These will afford a few early potatoes in succession to those planted in the frames. When the stems of the potato appear above ground, the radishes should be cleared away from them as fast as they become fit for use. After the seed is strowed over the surface I cover it, not by raking it in, but by sifting some earth over it with a sieve: on so small a scale it costs but little extra labour, and the seed vegetates much more regularly over the surface. With the back of my spade I then make the earth firm, and then cover the whole with some short straw litter. This litter is not removed till the seed vegetates, and the bed is covered again on the slightest appearance of frost. This covering is never removed entirely until the plants are sufficiently strong to withstand the effects of any after frosts. There is one thing that you must guard against by watchfulness, and that is in not allowing the covering to remain on the plants too long at a time after they have vegetated, as they are apt to be drawn up weakly, and rendered useless. It is just in this sort of management that skill and watchfulness win the day, and this skill and watchfulness must come from within the cultivator; it cannot be derived from books. All we can do is to point out what is required, and then leave the matter.

Jno. F. McELROY.

HOW TO PLANT GARDEN TREES.

Our modern method has the merit of being rational. It looks upon roots as organs to be preserved, and not useless appendages to be mutilated or destroyed at pleasure. It recognises the importance of giving them a fair start in the best possible direction; it acknowledges that they are worthy of room; although necessity compels us to bury them out of sight, they are never on that account out of the modern cultivator's mind. One of the most singular revolutions in horticultural practice is the additional interest that is now taken in the roots of plants. Ancient cultivators operated on the trunks and branches chiefly and directly. They sought to induce fruitfulness by barking, ringing, twisting, and cutting them in various ways. Modern horticulturists achieve the same result much more speedily and successfully through the medium of the roots. Root culture is therefore not only of the highest importance in itself, but it has modified and altered our treatment of all other parts of the plant; hence planting now, instead of being performed in a haphazard rule-of-thumb sort of way, is conducted with more care than almost any other operation in gardening. Before planting, take a survey of the roots of the plant, and measure their length; then, from the point where the bole of the tree is to be placed sweep a radius right round if the tree is to be placed in the open ground, or half round if against a wall. From this semi or whole circle remove the soil to a depth of six inches, or less for very small trees; then tread down the bottom quite firm and make it even. If the soil is naturally strong or wet, no earth need be thrown out at all, but the preliminary operations of levelling and consolidating may be made on the surface itself. If only moderately strong, the hole might rise slightly from the centre to the sides. Under no circumstances should it fall from the centre to the circumference; and as a rule the bottom of the hole for the roots should be perfectly smooth and quite level. Over this carefully-prepared base a thin layer of compost, consisting of equal parts of sweet leaf-mould and loam, may be spread. On this the tree is to be placed; fix it at once to the wall or fence, or to a stake, to be now driven into the ground for this purpose. There are two great advantages in placing the stake into the ground at this stage; one is that no roots can be destroyed by its insertion afterwards, and the other that, by fixing the tree at once loosely to the stake, both hands are left free for the great operation—and it needs them both, and a nice head to guide them, to root a plant skilfully and well. With a sharp knife in one hand, and a root in the other, begin the process of laying out the roots to the best advantage. Handle them as tenderly as if every rootlet was endowed with sensitive feeling. Cut off with care and precision every broken and bruised part; let the whole diverge from the centre to the circumference like the spokes of a wheel, or the branches on a well-formed fan-trained peach-tree. Let there be no entanglements nor interlacings; give each root its own line of sway. The operation is a nice and delicate one, and must not be hurried through. It constitutes the basis of success, and it is as notably important in the science of horticulture as in that of architecture that the foundation should be "well and truly laid."

Having satisfied ourselves on this point, the next proceeding in the operation is that of filling in or up. First should come a covering, about two inches thick, of the same compost as that placed beneath the roots. Then the whole of the other earth should be broken fine with the back of the spade. It should then be sprinkled or scattered over, not thrown in heavy spadefuls upon the roots. The soil should be so placed as not to need any levelling afterwards. No foot, nor spade, nor rake should be allowed to touch the charmed circle devoted to the roots. If the trees are placed on the natural surface, of course when the operation of planting is completed an artificial mound will be raised on to the top of the roots. In such cases the covering should be a few inches thicker than when the roots are under the natural level.

The only consolidating agent we allow is water, and even this may safely be dispensed with when the soil is wet. In other cases, the earth may be washed in with from six to a dozen gallons of water, applied over the entire surface of the roots through a coarse rose. The more rapidly it is applied the more efficiently it will act as a consolidator of the earth. In a few hours after watering, the surface should be covered over, or *mulched*, as it is called, with a layer, about three inches deep, of half-rotten manure, cocoa-nut fibre, moss, or such material. This exerts two influences, each of the greatest consequence. It prevents the earth from becoming dry, and protects the

roots from frost. The latter is of vital moment. For although an excessive activity of root action in winter is to be discouraged, yet it is most essential that any rootlet that may venture forth (at this season) should be preserved from injury or destruction; hence the planter's motto for the first winter should be, no frost admitted to a single root.

A curious caution needs to be given here. Beware of hanging the newly planted tree. The firm bottom so much insisted on is a good antidote against this danger. But no amount of artificial consolidation will arrest the further subsidence of recently moved earth. It thus happens that when trees are firmly attached, as we have advised them to be, to either walls, fences, or stakes, they are often suspended as it were between the earth and the air, as if they belonged to neither. Under such conditions the roots have to support the whole weight of their covering soil, and are often ruptured or unduly strained by the heavy load. From this hidden cause frequently spring forth the germs of constitutional debility, disease, and death. The remedy is simple. In fixing the tree securely against any violent horizontal movement, see that one end of the tie is so arranged as to admit of a vertical depression. With this freedom of movement downwards there must, however, be combined resistance to horizontal motion. Otherwise, just as the roots lay hold of the soil their tender and delicate points will be broken off by a change of place. A succession of such deprivations will prove as injurious to health and as fatal to strength as hanging itself. Practically, there is no difficulty in securing the one while providing against the other, and the two combined constitute the perfect art of fixing newly-planted trees.—*The Field*.

Calendar.

WORK FOR WEEK COMMENCING DECEMBER 21.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—There ought not to be now a single square yard of unoccupied ground that has not been deeply dug since the last crop was taken off. Deep stirring and successive frostings of the soil are immensely beneficial, and there will never be much success in the culture of edibles where there is any fear of hard work in winter. The outdoor work of this month must be regulated by the weather. When the ground is not fit to be trodden on, get together all the clippings of hedges, prunings of trees, &c., for charring, and keep the produce under cover to use as needful; it is a most valuable top-dressing for peas and other early crops, both to stimulate growth and prevent attacks of slugs. During frost, wheel out dung, ready to dig in at the first opportunity. Sow, during fine dry weather, Dillistone's Early and Sangster's No. 1 peas, Mazagan, Longpod, and Beck's Gem beans, Horn carrot, and hollow-crowned parsnips. We have found of late years that parsnips sown at the end of January make very heavy crops, and are rarely hurt by frosts; and if they do happen to be cut off by frost, there is still time to sow again, and the loss of the seed is a very trifling matter compared with the chance of a heavier crop.

PEAS AND BEANS may be sown now in frames, to transplant when the season is sufficiently advanced. These will be useful to replace any outdoor sowings destroyed by frost, and to mend and patch the rows that have suffered damage. The best way to sow for transplanting is on strips of turf, which can be lifted out and laid in the rows when the transplanting takes place.

ASPARGUS, SEAKALE, AND RHUBARB will now be coming in plentifully from the forcing-beds. If these beds are allowed to get too dry, the produce will be neither good nor plentiful. But they may be moist on the surface, and yet dry at the roots of the plants; therefore ascertain by stirring the soil with a trowel in the middle of the bed, and if dry give a good soaking with tepid water. Make up fresh beds for successive supplies. In ordering in roots for forcing, take care either to plant immediately on receiving them, or keep the roots moist with moss or mould, or they will be much injured by the action of the atmosphere.

COMPOST should be prepared in quantity, as there is now a chance of getting it well frozen and several times turned before the winter is over. The benefit of attending to this at once will be immense in the culture of specimen plants, and, in fact, with whatever requires a good compost, well pulverized, and free from vermin. It must be remembered that composts frequently turned at this time not only get frozen, which kills the vermin, but the robins and thrushes explore it every time it is thrown up afresh, and they, perhaps, clean it more effectually than frost.

WARM BORDERS sloping to the south under brick walls may be sown with Horn carrot, Early Short-top radish, white mustard, golden cress, Beck's Gem beans, and Hammersmith lettuce. During sharp weather, dry litter and hurdles will protect them very efficiently.

Flower Garden.

FLOWER GARDEN.—We cannot advise the planting of evergreen shrubs at this season, though we confess to doing it ourselves, and seeing it done by everybody else. It would be much better for the trees to be content now with marking the places where they are to go by stakes, and leaving them untouched till April, when the shift will distress them less, and they will commence to make new roots immediately. This plan allows of the planting of deciduous trees and the finishing of all the rough work in laying out a shrubbery; and it may even be carried so far as to the making of the holes for the evergreens, laying the stuff taken out in heaps beside them, to get completely pulverized for filling in. Every cultivator of flowers should secure now a good supply of turf from a loamy pasture, and of bog, peat, or silky yellow loam in which the common brake grows plentifully. These should be stacked up in high ridges like walls, so that the frost will penetrate the whole mass, and the grass will rot quickly. Manure, roughly spread among choice shrubs, will assist in protecting their roots from frost. In spring the manure can be levelled, and all rough stuff raked off. This is a good time to make banks and rockeries, as during frost the wheeling can be done without harm to the walks.

RHODODENDRONS that have been many years planted require a little refreshing at the root, and this is the best time to do it. A mixture of very rotten cow-dung and leaf-mould is an excellent surfacing material, or two or three inches of rotten cow-dung only will do; nothing stronger must be used. This is a job that may be done during frost better than while the ground is wet.

ROSES requiring protection, and hitherto neglected, must have attention at once, as we are now approaching the season of real winter. Plantations of Roses should now be mulched with half-rotten dung, the looseness of which will protect the roots from frost, and the drench of rain and

snow will carry much of its goodness into the ground. Roses to be planted should be got in without delay while there is yet a chance of fair weather, as if neglected now it will be better to defer planting till the end of February. All newly planted standards are to be securely staked. In damp soils iron rods are the best stakes, as they do not encourage mildew in the soils, as wooden ones do.

TENDER PLANTS in the open ground, such as Fuchsias, Erythrina, Bouvardia, Oxalis, Alstroemerias, Japan Lilies, Watsonias, and other rather delicate bulbs in the peat-bed, must have some protection, such as coal-ashes piled in the form of a cone over their roots, or heaps of moss put over, and kept from blowing away by means of hoops of willow rods.

Fruit Garden and Orchard House.

FRUIT TREES of all kinds, both in fruit garden, orchard, and orchard house, should now be pruned and painted. For the latter purpose a mixture of lime, soot, and clay, to the consistence of paint, will answer well; or use Gishurst's compound according to the directions which accompany it.

Greenhouse and Conseratory.

CHRYSANTHEMUMS may be disposed of very easily by setting aside in a cool greenhouse one store-pot of each variety it is intended to propagate, and destroying all the rest. That is our way of wintering a large number in a small space. Good stools in six-inch pots will furnish any number of cuttings when required. People who have no glass can pack the roots close together under a wall or fence, where some dry straw can be thrown over them during severe frost.

|| GARDENIAS.—*G. radicans* is a well-known and very favourite greenhouse shrub; it is a native of China, and was first grown in England in the year 1804. As a greenhouse plant it has scarcely a compeer in fragrance or beauty; in its native country too it is very highly prized. The Japanese, as Thunberg relates, form hedges of it, and ornament their houses and the walks of the gardens with it, and other species of *Gardenia*. This is one of the very limited class of plants suitable for window culture, and there are only three of this genus which bear the character sufficient to warrant the prenomens: these are *G. radicans*, *G. Thunbergia*, and *G. Rothmannia*; the remaining species are all properly stove plants. A difficulty is often experienced in the blooming of these plants, more especially the greenhouse kinds; sometimes the plants do not produce any flower-buds at all, and others may bring a sufficiency of buds; but they as often fall prematurely, much to the disappointment of the fair owners, for this genus is a most decided favourite of the ladies. It may be useful to endeavour to trace the cause of this premature fall of the flower-buds, as the knowledge of the true cause of a failure is the first and most essential step towards the application of a remedy; these plants, when in a state of nature, inhabit a portion of the globe where the seasonal changes are very great, and consequently the seasonal growth of plants equally marked. Indeed, so severe are the winters in some parts of the eastern world, and the effect of this tending to render the plants constitutionally robust, that, was it not for the greater humidity of our climate, we might be justified in the expectation of acclimatizing all the plants of those countries. The effect of this has been already explained as instances have arisen, therefore what is now required consists chiefly in a practical view of the case. The plant, when placed in a room as a window plant, is subject to one undeviating atmosphere, the temperature of which is kept as as nearly the same as possible, and, through a mistaken kindness, supplied with water just as regularly. This is clearly the opposite of the plant in its natural state, for then during the summer months it has the full influence of the sun, with the benefit of the free air; and in winter, its only advantage is its annual covering of snow, just sufficient to protect it from the effects of frost, and which yields but very little humidity until it becomes thawed; and the same cause, namely the power of the sun, which supplies the plant with moisture by dissolving the snow, acts immediately on the energies of the plant, throwing it into a growth as luxuriant as it is sudden, and it is by this the treatment of the plant when in an artificial state should be regulated. In the autumn, let the supply of water be gradually but certainly diminished, giving at last only just sufficient to keep the earth in the pots together; this should be continued from October till March, then let them be placed in a very gentle hotbed, if at hand, or in a warm window, or part of the greenhouse, but the frame is the best, the heat of which should be about 55°. The plants must not be plunged into, but merely placed on the bed, and from this time increase the supply of water and air, and a good bloom will be the result. After the plants have done flowering, they should be repotted in a mixture of loam and peat, or loam and old leaf-mould, and then place them out of doors, shading them for a few days from the intense heat of the sun till they become re-established, after which they should have all the sun they can get to ripen the wood, observing to give them plenty of water while growing. By the end of September they should be removed into the house, and the autumn treatment repeated. The remaining species are all, strictly speaking, stove plants; the finest of them is *G. Florida*, with its variety *fore-pleno*; these all delight in a mixture of loam and peat, with the addition of a little fine silver sand: a good drainage is always requisite. The season for repotting is immediately after flowering; they should never be over-potted, as they always grow best when the roots are touching the sides of the pots; after repotting they will be benefited by being placed in a cool part of the greenhouse; these, like the others, should be allowed to become dormant during the winter months, and started again in February. They may all of them be propagated by cuttings taken off in June, July, and August, and planted in a pot of sand and peat, and plunged in a very gentle bottom heat, covering it with a small cap glass. They strike readily. Though some care is necessary to keep the glasses dry, they should be wiped once or twice every day, and all symptoms of mouldiness removed.

Stove and Orchard House.

IXORAS to be near the glass, and have plenty of air as the weather will allow.

STEPHANOTIS to be potted and trained.

ALLAMANDAS to be potted and trained.

DIPLODENIAS to be potted and trained.

Forcing Pit.

FOREIGN FLOWERS.—Put in Provence, Tea, Bourbon, and Perpetual Roses, Sweetbrier, Lily of the Valley, Lilacs, Weigelias, and bulbs, according to stock.

ORCHARD HOUSES FOR TROPICAL FRUITS.—Orchard houses for stone-fruits have of late placed us in a more advantageous position for securing the presence of those luxuries on our tables, than when we had to depend on open walls for our supplies; and cheap glass, with the diffusion of practical knowledge, add to our luxuries grapes equal in flavour and beauty to the

productions of the sunny south. Why should we not proceed a few steps further, and produce at home the fruits for which we are in general dependent upon the sunny climate of Italy and other parts of the Continent, for many a nook about a house and premises might afford a site for a fruit-house of some shape or size; for there is no need to be fettered by empiric rules as to form or size, so long as a tolerably good aspect can be secured. And this may range from south-east to west, the other necessary conditions being the provision for warming, airing effectually, and the admission of all the light possible. A narrow house with perpendicular front lights, and span roof might often be made to cover an ugly wall, and afford an agreeable promenade in inclement weather. Supposing such a house, with a border two feet wide at the back, well drained of course, and filled with suitable soil, and another border of the same width in front, a walk between the two four feet wide, with a flow hot-water pipe running on one side, and a return pipe on the other side, to form an edging or kerb to the walk, a wire trellis on the back wall would serve for training oranges, &c.; a dwarf and a standard tree alternating; in the front would be a trellis about half the height of the front lights, say three and a half feet; on this the guava (*Psidium Cattlejanum*), the pomegranate (*Punica granatum*), the *Eugenia ugni*, and the *Physalis Peruviana*, commonly called Cape Goose, berry, may be trained, and to these may be added the olive if desired, whilst from a wire under the ridge of the roof might festoon the *Passiflora edulis*. The value of some of the above-named, especially the genus *Citrus*, and the pomegranate, consists not alone in their fruit-producing properties, but have for centuries been considered worthy of the cultivator's care for their flowers alone, or at most for their general ornamental appearance; for if we take a retrospective view of the culture of these plants, we find them cramped in ugly pots or boxes, with the view of stowing them away during winter in opaque-roofed houses, to be the more readily dispersed about the gardens in summer as rare ornaments. Under such circumstances the fruit seldom attained anything like perfection; but we have on record exceptions to the above rule, and these exceptions proved that they were worthy of better treatment, for, in cases where they have been planted out, and grown either as standards or trained against the back walls of forcing houses, they have produced abundant crops of fine fruit. Of the utility of the other fruits above named, we may remark that the appreciation of them depends in some measure on individual tastes, but that is not the view in which most gentlemen regard such things. Many of the dishes that are sent to table might as well remain elsewhere; but as they are sure to find some admirers, and at any rate afford diversity of an uncommon order, that would be sufficient inducement for their adoption, as it is become an important matter, since the present style of giving dinners "à la Russe" has obtained favour, to display a handsome dessert. Of the history of the *Citrus* tribe, Loudon gives an interesting epitome in his "Encyclopædia of Gardening," in which he says "the citron was introduced into Europe from Media, and was first cultivated in Italy by Palladius, in the second century."

The ORANGE is supposed to have been introduced into Italy from India, and into England in the sixteenth century from Italy. All the species endure the open air at Nice, Genoa, and Naples, from whence large quantities of trees are exported to other countries, many of them, it must be confessed, in a very careless manner, being merely tied in bundles, and wrapped in mats or straw, in which state they may be obtained, at a low price, from the Italian warehousemen and seedsmen in London. And if time and proper attention can be afforded them they soon recover themselves and make splendid trees, as they generally possess clean and straight stems; but if immediate effect is desired, and expense not an object, fine plants in flower and fruit may be obtained of the nurserymen, who import them in tubs and boxes. Should a batch of the first-named trees be obtained, the first thing to be done is to arouse their dormant energies, by means of a tepid bath, which must be kept to a uniform temperature by additions of warm water for the space of twelve hours, or longer, if the trees are very dry; should the vessel in which they are plunged admit of it, they may be laid down root and branch in the water; if not, the roots must be plunged, and the stem and branches be kept moist by syringing. When taken from the bath, they may be covered in moist hay or moss for a few hours, or a day, by which time it will be seen which roots are plump and fresh, also which of the branches are likely to push strongly; then cut away all injured parts, both of the roots and branches, but before the trees are procured, it will be well to consider what is to be done with them, and whether everything is in readiness to insure them proper treatment when they arrive, if it is determined to plant them at once in the place they are to occupy. The border should be in readiness by forming a drain at the bottom, and upon that place a foot in depth of broken bricks, upon which should be two feet in depth of prepared soil, in a comparatively dry state, the soil to consist of partially decayed turf from a pasture—no substitute for this will do—with a small sprinkling of inch bone, of charcoal in small lumps, and of coarse drift or river sand. The latter ingredients are to keep the soil in a free and open state, consequently, to be used in larger or smaller proportions according as the compost is porous and friable, or tenacious and heavy, the orange preferring the latter description, provided sufficient of the rectifying ingredients are used to keep it open and pervious to moisture. Manures may be added in moderate quantities, but must be old and reduced to a black mould, cow, sheep, or deer dung being best, as they are cool in their nature; hot stimulating manures are exceedingly injurious to the orange. In order to give the trees a start, when planted it will be well to have in readiness a heap of well fermented stable manure with which to cover the border between their stems to the depth of twelve or fifteen inches, the stems in the meantime to be protected by hay bound round them; it can be removed when the trees are become somewhat established. Early in spring is the best time to procure the trees, as their growth will then proceed without check; should, however, the house and border not be in readiness at that time, the trees may be potted in large pots or temporary boxes, and be plunged in a tau or other bed in any vinery or other house in which is kept a moist and warm temperature, and can afterwards be transferred to their permanent place. Should it be wished to plant out trees that have long stood in pots or boxes, it will be well to choose either spring or autumn for the operation, and if the soil is sour or the roots much matted, clear them of all the soil by plunging the ball in a tub of tepid water, and after having soaked for a time, lift it up and down until all the soil is freed from the roots, then prune away any that are decayed, separate and disentangle others, and having ready a hole sufficiently large to spread the roots in, place the tree in its place, shake in the soil between the roots, and water with tepid water. It will be well at the same time to relieve the head of the tree by pruning away all small useless branches, so as to admit light and air to those that are strong enough to produce the fruit; a warm atmosphere, with frequent syringing, must be maintained with newly planted trees

established in their new quarters; afterwards the general treatment as hereafter given. Those persons who may not be in a position to plant out their orange trees, but grow them in pots or boxes for special reasons, are often grieved by the yellow and unsatisfactory appearance of the plants notwithstanding all their attention to their wants. This often arises from imperfect drainage and sour soil; the presence of worms often occasions this; their best remedy in such a case is to have recourse to the tub of tepid water, as above described. Clear their roots of every particle of soil, and repot in fresh, such as is described for the border of the orange house, not using pots over-large for the size of the trees, but just of sufficient capacity to hold the roots without squeezing or cramping; when potted, cut back the branches so that when the tree breaks afresh it will form a symmetrical specimen; plunge the pots in a warm medium, and syringe as before directed for trees planted out. After they have made fresh roots, and some degree of growth, they will then bear to be withdrawn from the hotbed of tan or other matter, but will be benefited by being kept in a rather warm house until July, after which they may be hardened off to stand for a few weeks in the open air, or a common greenhouse. But before returning to the orange house, it will be well to say a few words respecting the conditions necessary to be observed, with respect to keeping the orange in health and vigour in pots. The chief evil to be guarded against is the disarrangement of the drainage, and consequent stagnation of moisture in the soil; therefore means must be used at all times to keep worms from entering the pots, whether the plants are standing on the floors of houses or in the open air; therefore, if the tubs are not raised on feet, they, as well as pots, should be set upon something to keep them clear of the ground. If pots are used, make the hole or holes at bottom much larger than they are when received from the pottery; this may easily be done by a small hammer. Boxes likewise must have holes of considerable size at the bottom. Over these place large potsherds, and upon them two or three inches in depth of lumpy charcoal, and pieces of bone, then a layer of coarse lumpy compost, and upon that the tree may be placed. Work the compost well between the roots with a pointed stick, giving the pot or box a rap occasionally upon the potting bench until filled to the rim, when considerable pressure with the hand must be applied, for the trees will do better when tightly potted than when loosely potted, and the soil not be so likely to get disarranged by watering. Water should in no case be applied until the tree is removed to its place, so that it has not to be jarred and shook about immediately after the water is given; the reason for this hint must be obvious, as any one knows that to shake about a top of wet soil is to convert it into a lump of brick-earth. If care is taken from the first to exclude worms, the water will pass freely through the soil, and at every watering enough should be given so to pass through; but should by any accident a worm get in, it may generally be brought to the surface by running a pointed wire into the soil and gently shaking it about, when the intruder may be caught. To established trees liquid manure may be given, made as follows: To one bushel of cow, deer, or sheep dung, add one peck of soot, upon this, when put in a tub, throw about ten gallons of boiling water, let stand for a day or two, take off the scum, then add ten or fifteen gallons of soft water, and it will be fit for use, and may be given once a fortnight during the growing season; the above will also be applicable to trees growing in borders, to which we now return. And supposing the trees planted, and the border covered with hot well-fermented dung to the depth already named, it will impart a genial warmth to the root, and also a considerable degree of humidity to the atmosphere, which, with light syringings with warm water, at three or four o'clock p.m., and a temperature kept up to 65° by night, and 70° to 75° by day, will speedily bring the trees into active growth, when their shoots must be trained and tied to the trellis, and if any appear too gross they may be stopped when two feet long, by pinching out the point, and if they break too thickly from the old wood, the weakest shoots may be thinned out. The manure must be removed from the border when exhausted of its heat, and as the season advances, the temperature may be allowed to advance by sun-heat to 85° or 90°, if with air on at the same time, but there will be no necessity for exceeding 70° to 75° by fire-heat. Air should always be given early, for if the sun breaks upon the foliage before the latter gets moderately dry, it is apt to disfigure it. As the trees get into free growth syringing must be discontinued, excepting occasionally when cleansing their foliage, and water instead be thrown upon the floors. If this is done in the afternoon of fine days, it will afford sufficient moisture. Air must also be increased as the season advances, so that in autumn the wood gets well ripened and fit to pass through the winter, when the temperature for the winter must be reduced to from 40° to 45° night, 45° to 60° day. If scale or dirt accumulate upon the foliage, sponging with soft soap and water must be had recourse to, and for this tedious operation a woman will do the work better than a man. For excellent advice on cleansing the orange, see an article by Mr. Chitty, in the October number of *Floral World*, 1861. Of course the foregoing remarks apply to all the citrus tribe that are likely to be cultivated in the fruit-house, and in general to the other fruits here classed with them, though some slight modifications as to soil, &c., will be necessary. The varieties of orange best adapted for general purposes are the Seville and Maltese, the Maudarin and St. Michael's. These are free-growing, free-flowering, and abundant fruit-producing varieties. Many others may be grown for variety, if space can be found for them.

THE CITRON offers several curious varieties. The best, perhaps, is the Madras citron, and though the fruit is seldom brought to the dessert in a raw state, it forms excellent preserves and sweetmeats to furnish the table when other fruits are scarce.

THE LEMON is well known, and generally esteemed in confectionery; the common variety is as good as any.

THE LIME, of which there are also several varieties, is used much in the same way as the lemon, and makes a pretty variety with the other fruits. The same may be said of the SHADDOCK, but for a different reason, the fruit of the former being the smallest of the group, whilst that of the latter is perhaps the largest. The citrus tribe should occupy the back wall, as they will there be slightly shaded by the *Passiflora edulis* on the roof, and the other fruits occupying the front trellis. It may here be remarked that they will be benefited by a very thin shading of net, in spring and early summer, until the other things afford them a natural shade.

THE PASSIFLORA EDULIS will thrive in any good soil, and may be planted in the end of either back or front border, but its roots are very encroaching; therefore, a space should be partitioned off for it, so that it does not interfere with the other plants. It may have one main stem carried under the ridge of the roof; from this lateral shoots will proceed on either side; on these the fruit will be borne. These must, every winter after the fruit is gathered, be cut back to within an inch or two of the main stem, as the fruit is only borne on the current year's shoots. The fruit, when ripe, is of a purple

colour, consisting of a tough rind, within which the edible pulp is contained.

THE POMEGRANATE (*Punica granatum*) is not alone worthy of culture for its singular and pleasant fruit; but, like the orange, has been much esteemed for the beauty of its flowers. Success in fruiting this plant depends much upon the proper ripening of the wood in autumn; consequently, the weak shoots should be thinned out, that those bearing fruit, as well as the main branches, may receive all the benefit of the sun and air circulating amongst them; those left should be closely trained to the wall or trellis, and at the winter pruning strong shoots should be shortened back, so as to get a supply of moderately vigorous young wood from every part of the tree, as only upon such is the fruit produced. This tree thrives in the soil recommended for the orange, with the addition of a sprinkling of old mortar and brick rubbish amongst it. Liquid manure or top-dressings of old manure may be applied as for the orange, in order to keep up a moderate degree of luxuriance; too much, however, will only produce coarse unfruitful wood.

THE GUAVA (*Psidium Cattleianum*).—The soil for this should differ from that recommended for the foregoing, and should consist of turfy loam and peat in equal proportions, with a sprinkling of old leaf-soil and silver sand; pure soft water only should be used for this. Pruning is required to keep the tree sufficiently thin for sun and air to reach the fruit, and for keeping the tree in proper form. The fruit is juicy, and in consistence much like a strawberry, to which it bears some resemblance, but with a slightly turpentine flavour; notwithstanding which it is highly esteemed by some.

THE CAPE GOOSEBERRY.—This belongs to the Solanum tribe; notwithstanding which its fruit, which is a yellow berry, within an inflated calyx, and ripens at all seasons, is wholesome and particularly agreeable when the palate is once used to it; it is also used in tarts. The plant may be propagated either from seeds or cuttings, and is of easy culture; in fact, apt to grow too gross, unless its roots are somewhat confined; it is, therefore, best to plant in a nine or ten inch pot, and plunge in the border so as to cover the rim with soil. As many roots as is thought proper can then be allowed to pass over the side of the pot into the border. This plant is subject to the red-spider; the syringe should, therefore, be well plied upon it to keep the enemy under. Training and tying to the trellis or pillar must be attended to, and its shoots and larger leaves be kept moderately thin by pinching.

THE OLIVE is a low branching evergreen plant; the flowers are produced in small axillary bunches from wood of the former year; the fruit is a berried drupe of an oblong form and yellowish green colour, but turning black when ripe. Unripe olives often appear as a pickle, both at dinner and dessert; and though to those who taste them for the first time they appear harsh, yet soon become extremely grateful, and are thought to promote digestion and create an appetite. The soil for this plant should resemble that above recommended for the pomegranate, and as this tree produces its fruit on the former year's wood, a portion of the shoots should be shortened or spurred back every winter, so as to insure a supply of wood of the proper age for fruiting. Strong imported plants should be planted, as young plants are long before they arrive at a fruit-bearing state. This, like the others, should be trained to a trellis, and its shoots kept moderately thin, so as to insure the ripening of the wood.

THE FIG is a fruit as well worthy of the gardener's care as any fruit grown; for though it ripens in favoured situations out of doors, it can only be so produced for a very limited period in each year; but under glass, by using a variety of sorts, the season of their ripening may be much extended, as several varieties will ripen two crops in each season, and the choice kinds can be had in greater perfection. Young fig-trees are very gross in their habit of growth when unlimited space is allowed to their roots; consequently, not arriving at a bearing state so soon as those having their space somewhat limited. If the border for these is made three feet wide, the soil need not be more than eighteen inches deep, resting on a foot in depth of well-rammed brick rubbish; the latter is necessary both as a drainage and to prevent the roots penetrating the subsoil; even in a border thus formed, it will be proper to lift the trees every year or two, according to their rate of growth, until a fruitful habit is secured, returning them back into their places immediately, and keeping their roots near the surface of the soil. If the above plan had always been practised, we should never have heard of the malpractice of ringing, which old gardeners had recourse to. It will, however, under such circumstances, be necessary to water freely in the growing season, and even to apply liquid manure to trees some years established and carrying heavy crops, for, should watering be neglected in hot weather, the fruit will fall off before arriving at maturity. Pruning should be done in summer, and that before the season is too far advanced for the wood to ripen, and should be principally done by pinching with the finger and thumb, so as to keep all growths short and the tree compact, yet sufficiently thin for sun and air to penetrate to every branch. The sorts to be relied on for two crops are, Brown Ischia, Black Genoa, White Genoa, and Black and Brown Italian. The larger and later kinds are the Murray, Brunswick, Brown Naples, &c. The fig in houses is best grown as dwarf standards, unless where they are trained to a wall or trellis; even then a stem a few inches in length should be kept clear of branches, otherwise coarse watery suckers are apt to rise from about the collar of the root; and these, when they show themselves, should be rigorously kept down. As the fig is subject to red-spider, copious syringings must be applied in hot weather.

THE NEW ROSES.

It is said that the following are the best of the roses now offered to English buyers. For my own part, I shall buy the four of which I give the raisers' names in parentheses: *Baronne Haussmann*, *Deuil de Maximilien*, *Duchesse d'Aosta*, *Elie Morel*, *Ernest Boncenne*, *François Fontaine*, *Impératrice Charlotte*, *La France* (Guillot fils), *Madame Girodelle* (Charles Verdier), *Madame Roland*, *Madlle. Christine Nilson*, *Merveille d'Anjou* (Trouillard), *Pitord*, *President Villermoz*, *Prince Humbert* (Margottin), *Souvenir de François Ponsard*, *Vicomtesse de Vézins*.

VIATOR. ✎

THE CHRISTMAS MOON AND THE HARVEST.—There are many locally accepted agricultural axioms that are worth noting, and probably acting upon. Said one of my ploughmen to me to-day, "We shall have a heavy harvest next year, because there will be a dark moon at Christmas—a new moon on Christmas-day." The other ploughmen assented, and said, "It had been noted by very old men for many years that a light Christmas moon gave light sheaves, and a dark Christmas moon gave heavy sheaves." They had themselves observed this, and called to my mind that the last two Christmas moons had been light or full moons. The dark or new moon takes place this year on Christmas-day. So let us hope that next year we may be blessed with an abundant harvest.—*J. J. Mechi*.

Replies to Queries.

F. Stephens.—A figure of Maréchal Niel rose was published in the *Illustration Horticole* for April, 1866. Possibly the surest way to obtain it would be to write direct to M. A. Verschaefelt, 50, Rue du Chaume, Ghent, Belgium, enclosing three sixpenny postage stamps to pay for book and postage.

Plants for Cool Greenhouse.—H. II. W.—We could more easily tell you of a hundred than a dozen, and it is all the more difficult to select seeing that you require them for exhibition. We will take six flowering plants first, and they shall be, *Chorozema Henchmannii*, *Correa picta superba*, *Desfontania spinosa*, *Epacris miniata splendens*, *Eriostemon pulchellum*, *Leschenaultia biloba major*. For six fine foliage plants, *Latania Bourbonica* (or *L. rubra*), *Yucca aloifolia variegata*, *Chamærops humilis*, *Echeveria metallica*, *Lomatia ferruginea*.

T. Taylor.—You will find an article on *Lobelia* in the Magazine of April 28, 1866; and articles on *Violas* in the issues for March 24 and December 8, 1866.

Roses.—O. P. Q., junior.—If you strike roses from cuttings in autumn, you may lift them from the bed and pot them in April, and, in fact, that is the right procedure. It is a good plan to place them when potted on a hotbed in the open air (without frames or lights); a free vigorous growth is thus ensured the first season. Grafts put on manettis in February may be from forced plants or from outdoor plants—that must depend on the condition of the stocks. If the stocks are in the open ground, then the grafts must be from plants in the open ground also, or, at all events, from plants that have been out all the winter.

Tan-bed.—Alice.—Tan is not often recommended, because it is generally less easily procurable than stable-manure, and it requires more judgment to use it to advantage. But when the right sort of tan is obtained, and is used in the right manner, it makes a lasting hotbed, far superior in equableness and continuance of temperature to the best stable-manure. As you are circumstanced, tan is the very stuff you want, and your pits are admirably adapted for it. In the first place, get clean tan—that from the lead-works is useless. Throw it in a heap for ten days under cover, then fill the pits with it, observing that it should be damp throughout, *not wet*. A depth of two feet will secure a lasting heat; better three feet, better still four feet. Immediately after filling the pits, begin to start your plants for cuttings, plunging the pots to the rims in the tan. Have also plunged in the tan a thermometer to give warning of a rise. When the heat rises above 60°, or at the utmost 70°, as no doubt it will, lift up the pots and place empty pots inverted under them, to prevent burning of the roots. After the first rush, the heat will gradually subside, and will remain for months at about 65°, and will carry you safely through all your spring propagating.

Vines.—J. J. M.—Training on a wall under glass is not by any means so good a plan as training under the glass, by means of wires attached to the rafters, as when on the wall the vines are too far removed from the light. We cannot encourage you in the plan you propose. In any structure such as you propose, it would be desirable to afford room for the cultivator within it.

Ozon.—The mites you send are *Gymnogrammas*. If you want to learn French, begin with Cobbett's French Grammar and a French Dictionary.

Horticultural Exhibitions.—Laird and Sinclair.—Your questions are best answered by a reference to facts. The great shows at Regent's Park, Manchester, and Kensington, have been held under canvas, the tents being on the ridge and furrow principle, and comparatively low in altitude. In these cases the plants have been seen to the best advantage, the attendance of visitors has been large, the returns have been satisfactory, and, as a rule, the plants sent have suffered little. In the great "suspension tent," which was erected under the direction of Captain Powkes at Kensington, and which was at first used for an exhibition of rhododendrons, a span-roof of lofty altitude was adopted, and the grandest specimens in that tent look dwarfed and poor; the great aerial space above them renders them pigmies by contrast. In those places in the provinces where the most successful exhibitions are held—such as Taunton, York, Leicester, Peterborough, &c., &c.—tents are invariably employed, and they have the advantage usually of being pitched in some pleasant spot, which people bent on a holiday prefer to the most elegant room in the midst of a town. One of the most thriving provincial societies, that at Cambridge, has long been accustomed to hold spring and summer shows in the Guildhall, but lately has taken to tents and gardens, and was highly successful with its exhibition, held in tents in the grounds of St. John's College, in May last. You really ought to have included in your query some reference to the seasons, as when we approach the time of year when outdoor pleasures are at an end, there is nothing left but to obtain large halls for exhibitions. Thus the exhibitions of chrysanthemums are always held in halls. The Birmingham Rose Show is the only really successful exhibition on a grand scale which we can call to mind as held in a building in the centre of a town, in the height of the summer season; and we are inclined to believe that the Birmingham Rose Show would be more successful if held in a great tent in a pleasant spot, at the distance of a short drive from Birmingham. To attempt general replies to general questions, we would say that exhibitions in large halls usually cost less, are more convenient to visitors, and more secure for the plants than exhibitions held in tents. But, on the other hand, exhibitions held in tents are more attractive, first, because the effect of well-grouped plants and flowers under canvas surpasses the utmost that can be done under any other kind of roof, and secondly, because people like to quit a town when visiting a flower show. The town hall is doubtless the most convenient, but the tent is the most agreeable. Finally, we vote for the tent whenever and wherever it can have the preference, leaving the hall as an alternative for times and seasons and places when and where the use of tents would be out of the question.

Vines.—R. H. C.—Leave your vines alone, and hope they may do as well going down as they did going up.

J. H. W.—You are mistaken; the Somerset Gardener has told how to grow pears without a wall, and he has given his opinion as to the relative merits of peaches and pears. If you can do as well, do it; and if you cannot, you must allow him to express himself in his own way. At all events, we shall do so, and hope to hear from him again soon.

* * * In Mr. Muir's paper on "Unnailing Wall-trees," page 535, second column, seventh line from the top, the word "stopping" should read *stopping*.

ON THE UNNAILING OF PEACH-TREES.

I have often had a number of crude ideas pass through my brain concerning the above subject, and, having heard and read all manner of stuff about it, also having made a modicum of observations of my own, with which the hearings and readings got intricately mixed, the result was a kind of mental hash, made of everything a little, and not much use to any one; but, by the process of time, which reduces all things to their simplest forms, this small chaos has also been reduced to something like order; then, at a given signal from without, a small observation from another hand, all this accumulated matter shall be poured forth.

Now, to begin at the end, or middle, or wherever it may happen, I do not much care which, I will give at once the small observation.

We often see it about this time of the year—I saw it, I think, only last week—that you are to unnaïl your peach-trees, so that the weather may act on the wood and harden it. Now I want to know what is the use of nailing or of putting them up at all after they have grown part or all of their summer growth. I cannot help thinking that the readiest way of obeying this order is to do as I do, and not have them nailed up; they take an uncommonly small amount of trouble to unnaïl them *then*, and not much more to nail them, for they are by this system to do without either the one or the other.

I will here give my ideal of the round of cultivation for the peach. All the winter the trees to be loose and unnaïled. March, nail up and prune. May, disbud and thin the fruit; here note that green shoots left in the middle of the tree get much too strong, and sometimes exhaust to death some of the branches; therefore be chary about leaving them. June, July, August, September, October, let these growths continue, thinning them out only where necessary, being scrupulously careful to keep them *off* the wall, and nail up only such as are in danger of being broken by stress of weather. March, nail up and prune for the next year.

We thus, about this time of the year, see a full supply of nice stout, brown, blooming wood, about nine inches to a foot long, bristling from the wall, and defying all the attempts of vermin to lodge anywhere near it; and not only this, but all through the growing season the cleanness of a growth will generally be seen to depend directly on its distance from the wall; for then it gets all the wind and weather—which are both noted insecticides, almost equal to Fowler's—but when you go to work industriously to nail up, or by any other means to fasten up close these growths, you keep them in the shelter of the wall, and the various vermin tribes gather under their shelter and thrive.

Now I have heard of an invention called Foxley's beaded bricks, which was to provide us with the means of tying up our trees, and so avoiding the cruel injury which we inflict on walls by nailing; and the objection raised against these by some old fogey was, that they kept the wood from the wall and so prevented perfect ripening of it.

I also saw communications about peach orchards where they were to be grown in the open; I also know to my certain knowledge that in the nurseries peaches are trained up to stakes in the open, and there are no complaints about the ripening of the wood.

And now, why not commit all such mandlin excuses to oblivion, and say at once that for blooming and bearing the wood should be nailed down, but that *all growths for the coming year should be allowed freely to push outwards?*

In the same line, I will relate an incident connected with a few Morello cherries. These trees, against a south-east wall, were in themselves about one day's work every year in pruning and nailing, for which outlay we generally got about a peck of black aphid and six or seven cherries (would that the two had changed places!). This I got sick of; so one day we had them all up and planted them in the open, taking from them such wood as could be spared. The following season they were clean as new pins, and brought about a quart of cherries; another pruning of old wood then followed. This year they had nearly a peck of cherries, and now they promise well for next year. I have pruned nearly all the old wood out, and the supply of new and last year's wood is quite a picture, so full of spurs too, so clean, sturdy, short, and strong. Ah! catch me planting Morello cherries against a wall any more, that's all; or, for that matter, bothering about nailing my peaches all the summer long, when there are better things to do.

A. DAWSON.

Chiswick.

IS DRUNKENNESS RARE IN VINE-GROWING DISTRICTS?—The Rev. Dr. Bellows writes from Bingen-on-the-Rhine to the *Liberal Christian* of New York:—"It is much to be regretted that the friends of temperance have of late been trying to unsettle the opinion that drunkenness is rare in vine-growing countries. It is so patent in France and in Germany that intemperance in the form of drunkenness is a most exceptional vice, that only wilful blindness or partizanship could deny it. I do not recollect to have seen one tipsy man since I left Paris, and only one in Paris, and I have diligently sought the places where, in our country, they would be found. The truth is, wine is one of the most common and one of the most beautiful gifts of Providence; an article joined with corn in the praises of saints. The countries which possess it understand its use, and are just as little subject to excess in using wine as in using corn. Excess is found everywhere, and all Heaven's gifts are liable to abuse; but to expect France and Germany to give up wine or beer is absurd, nor would anything but harm come from the attempt to enforce their disuse by legislation. Special efforts must be made in northern climates to resist the tendency to strong drinks, which is aggravated by cold and by the necessity of harder work to live, not to add gloominess of weather, short days, and much darkness. I was somewhat horrified to find, later, in common use among field labourers, both women and men, in certain districts aside from the Rhine, a fiery alcoholic drink called potato-whiskey—strong, intoxicating, and full of fusil oil. It is part of the daily ration of field labourers in the region about Frankfort—a half-pint per day; and in harvest time even this does not satisfy them. They expend a certain portion of the extra pay of this season in adding to their whisky ration, and many of them then drink, I am told, to drunkenness. This is a proper deduction to be made from the universal temperance observed among the better classes, and should give some pause to the inquirer's verdict upon the sobriety of wine-making countries. Unhappily, the whisky is only twenty-three cents per gallon, and wine is many times dearer. It is, however, universally conceded that drunkenness is more and more rare even among this field class, and that it is wholly confined to it, with rare individual exceptions. I shall press the investigation wherever I find opportunity, and report results without fear or favour, be they in accordance with theories or expectations or no.

The Gardener's Magazine.

SATURDAY, DECEMBER 28, 1867.

HORTICULTURE DURING THE YEAR 1867 has certainly not retrograded, but, we would fain believe, has made some substantial advances. In our representative capacity we have to consider not only the progress of the science or the art, whichever it may be called, but also the nature and the result of every demonstration of its purposes, made in the presence of mankind at large. While, therefore, we reflect upon our acquisitions of knowledge and our progress in the improvement of opinion, we must bestow some attention upon the displays of the products of horticultural skill through which the public are advertised of the tastes that prevail amongst us, and the aims we cherish and desire to fulfil. Undoubtedly the most important contributions to our actual knowledge, and to the advancement of healthy opinion, in the past year, have been obtained for us from the Continent. It scarcely matters whether the gatherings of correspondents, and of one especially, whose privilege it has been to create unwonted curiosity and excitement in the horticultural mind,—it scarcely matters, we repeat, whether the particulars that have been made public respecting French practices in fruit culture be absolutely new or not, it is quite certain that to the majority of English cultivators, including the reading men amongst them, very much of the information made public on this subject is as new as if but now for the first time discovered. Our esteemed friend, "W. R.," has furnished to this sheet an admirable summary of the results of his explorations of French fruit gardens, in so far as relates to the modes of training which are most in favour, and in respect of which the prolonged discussion on the relative merits of English and French methods has waxed hottest. We do not hesitate to say that to him the whole body of English horticulturists owe a deep debt of gratitude, and we believe there are but few exceptions to the acceptance of his services as benefactions of the greatest value. The discussion has called forth the opinions of men best competent to speak on such a question, and the conclusions arrived at by the writer who set this ball rolling have been almost unanimously confirmed by the most experienced and far-seeing of English pomologists. That there should be an exception or two to the generally fair and generous spirit in which the several points of the discussion have been handled, need not surprise; indeed, we never expect public discussion to proceed far without being marred by dogmatism. But the lesson afforded is a good one; it is, that we may learn something of our neighbours if we go to them in a teachable spirit, and to advance our knowledge is of far more importance than to feed our pride. From the tone of some letters that have appeared, one might suppose that the matter of first necessity, irrespective of all facts, was to establish the absolute superiority of English practices above all the rest of the world, and to shut out light from whatever source, for fear our national vanity should be affected. How absurd! This tight little island is not the sole fountain of wisdom for the world; we may learn something by looking about us, and we rejoice in the belief that during the year 1867 we have been taught something useful in the matter of fruit culture.

The Paris Exhibition has contributed in some degree to the advancement of taste as well as of knowledge, irrespective of what we may now call the episode of the fruit-tree controversy. The manner in which the model gardens were formed and planted, and the success of the several features of which they were constituted, afford a salutary lesson on the great general subject of exhibitions. Extemporised plantations and instantaneous effects are as desirable in quiet times as in a season of excitement and novelty, and we hope for the time when our customary exhibitions will be accompanied with illustrations of scenery, climatal phenomena, and taste and style in garden architecture. In respect of all such matters, and making

full allowance for some inevitable bits of tawdriness, the out-door portion of the great Paris exhibition has afforded useful lessons, which are likely to bring forth fruit amongst us. Referring to our own exhibition season, we have every reason to congratulate ourselves on the increased and increasing interest manifested by the public in displays of horticultural productions. The great exhibitions of several days' continuance that have been held in several places, have proved successful in more cases than one, and there are but few modifications of rules and observances to be effected to render long-continued displays as acceptable to exhibitors as to treasurers and the general public. The effect of several good examples is to culminate in an expansion of the exhibition scheme, at the Royal Botanic Gardens during the coming season; and we hope for as complete a success for the two days' exhibitions announced to be held at Regent's Park as the society has become accustomed to in its eminently useful and honourable career.

The weather of the past year was equally unfavourable for horticulture and agriculture. A defective corn-crop was accompanied with defective crops of potatoes, fruits, and other kinds of garden produce. One general cause may be referred to in every case of a general failure of crops in this country, and that is deficiency of solar heat and light. Science has contributed largely to mitigate the evils incident to our isolation and the precarious nature of our climate, but there remains abundant room yet for discovery and improvement. Glass and coal have been the most beneficent amongst many of the new friends of the horticulturist; and it is but reasonable that in a country so densely populated, and where wealth and enterprise go hand in hand to multiply the comforts of life and enhance the beauties of nature, that the production of artificial climates should be considered by cultivators of plants as amongst the most important subjects to which invention and industry can be directed. There can be no doubt at all that the economical employment of glass and fuel is the one great problem of our time. Only within about five years past, some twenty or more patents have been taken out for improved (or supposed improved) forms of glass houses, furnaces, and other lighting and heating apparatus for horticultural purposes. Some of these merit attention by their extravagant complication and costliness; all of them merit attention as indicating the common consciousness of a want, and as pointing to work which yet remains to be done to render our daily share of sunlight, which is very small sometimes, productive in plant growth and the maturation of fruits to the full maximum of its power.

That we move slowly is but too evident in the general defectiveness, cumbrousness, and expensiveness of the majority of newly-adopted appliances. It is our bane that as horticulturists we shut out much of the light which enlarged views of nature would obtain for us. We construct plant houses without knowing much of the laws of light; we construct furnaces while in great part ignorant of the laws of heat; we engage in hybridizing and cross-breeding for the most part in ignorance of the laws of physiology, and it is but rarely the breeder of sheep and cattle and the breeder of garden varieties exchange notes with each other, or seek for any light beyond the sharp boundary line which they have drawn round their pursuits in a spirit as narrow as if they belonged to a separate world. The most accurate observation of minute particulars is consistent with a broad view of universal laws, and we shall not fear for any of the departments of the horticultural arts when practitioners of horticulture give their minds to the study of the laws and phenomena of nature in the largest manner, and in the conviction that every separate truth is but a part of the great whole which the Creator has set before us in His word and His works.

MANCHESTER NATIONAL EXHIBITION.—On the 27th of July last we announced (see page 319) that the council of the Manchester Botanical Society had resolved to hold a great show during the Whitsun week of 1868. It will be seen by the dates of the intended exhibitions of the Royal Horticultural Society that Kensington will again wage war with Manchester, and we may expect that Kensington will again be worsted. It is inexplicable on any other ground except that which men of honour and spirit must reject as having any proper place in this matter, that the council of the R. H. S. should fix the time for their first great show when it is impossible that the leading exhibitors can take an equal part in both, as they would do were

the dates sufficiently far apart. It is alleged that the great races occurring in May and June leave the council no alternative. Well, perhaps so; we are accustomed to find the council destitute of alternatives when direct injury and disgrace of the society they represent are imminent; weak and misdirected governments are always crippled for alternatives, and we must expect that the Royal Horticultural Exhibition, which is to continue from June 2nd to 5th, to prove as great a failure as that of last year, when, Manchester attracting the principal talent and the grandest collections in the country, the council of the R. H. S. made a pitiful appeal to exhibitors to allow their plants to remain a longer time than first agreed on, in order to make both ends meet. The Manchester Exhibition will open on the 29th of May, and close on the 5th of June next. The schedule is now being distributed. We observe amongst the prizes offered the following: sixteen stove and greenhouse plants, 1st £30, 2nd £20; twenty miscellaneous plants, 1st £30, 2nd £20; ten Azaleas, 1st £20, 2nd £12; ten Roses, 1st £14, 2nd £10; sixteen Orchids, 1st £16, 2nd £12. Other prizes are in like proportion; it will be understood therefore that this is a liberal schedule.

We regret to announce the death of Mr. William Clark, seedsman, of Bishopsgate Street, and Tottenham, who succumbed to an attack of apoplexy on Saturday last.

MY ORCHID HOUSE.—No. XV.

THE DENDROBIUM.

The popularity which this genus has acquired amongst orchid growers, and, in fact, amongst lovers of plants generally, whether growers or not, is abundantly testified by the number of species there are in general cultivation, and the number there are in individual collections. There can be no doubt the genus fully deserves the attention it receives at everyone's hands; for "fræe November till October" it contributes largely more or less to the beauty of the orchid house. Whether we take into consideration the handsome appearance which some present in their manner of growth, the graceful habit of others, the extreme beauty and diversity of the flowers which the different kinds furnish, or the profusion with which they are produced, together with the simplicity of the rules necessary to be observed to accomplish their successful cultivation and management, there is not another genus in the whole family of orchidaceous plants that can bear comparison with it. I am fearless of contradiction in making this assertion. If we take the whole of the good qualities collectively, unquestionably some of the Cattleyas, such as *Mossiæ*, *labiata*, and one or two others, would beat the best of the dendrobes in point of beauty; but then they are expensive to get at, and difficult to grow and flower after they are obtained, and the same may be said of other genera. But, take them "all in all," the dendrobes are decidedly the best for growers who are not lucky enough to possess separate houses for special purposes. Although they cannot be grown in such a low temperature as some of the *Lycastes* and the *Odontogloss*s, they can be grown more easily, and at the same time afford a large amount of beauty, that is, with few exceptions; for when the species are natives of New Holland, Nepaul, and Japan, the same temperature as would do for the *Lycaste* will suit them capitally. Amongst such as we may call cool species are, *chrysanthemum*, *Egertonii*, *heterocarpum*, *Kingianum*, *speciosum*, and *transparens*. The whole of the others are best grown in what is known as the East-Indian House. Ainery in full work will do very well until the grapes begin to ripen, when they must have fresh quarters provided them; for though some few others in addition to those enumerated above will live in a colder house, still it is a most difficult matter to keep them healthy, much less to persuade them to grow vigorously and flower well. The principal consideration in growing this genus is to push the plants freely when they are growing, so as to give the young bulbs every opportunity of attaining their full size early in the season, and before the shortness of the days and the dullness of the weather prevent their receiving that full amount of light which is so essential to their well-being, and to their flowering the following season. When the bulbs are properly matured the plants can be thoroughly and efficiently rested and, as I have remarked on one or two other occasions, so far as these conditions are kept in view and complied with, a more robust health can be expected, combined with a larger proportion of flowers. Unless the plants are grown strong, there will be nothing to produce flowers, and it follows as a matter of course, that unless the bulbs are ripened after they are grown, the flowers will be deficient in quality as well as quantity. In this respect orchidaceous plants in general, and the dendrobes in particular, are not at all singular in their requirements; for, take any other known plant, whether grown for fruit or flowers, no matter of what class, and no one having any knowledge of plant or fruit growing would expect fine fruit or flowers from half-starved plants with ill-ripened wood.

In cultivating this genus the natural habitat of the various species should be studied, and, as far as practicable, the different seasons of growth, rest, and flowering imitated. As most of the species are natives of different parts of our Indian

territory, it can be done with very little trouble; for, in the first place, we have the rainy season, when the plants make their growth; the cold season, when they rest; and the hot and dry season, when they flower. Although the different kinds vary in the time of flowering, they generally begin to push in March and April, when the plants should have the advantage of a temperature, to begin with, of 70°, combined with plenty of water thrown on the stages and floor, and with a syringe overhead once a day. As the days lengthen, and a large proportion of the heat is derived from the sun's rays, the thermometer may go up another ten or fifteen degrees, and the plants are then to be syringed twice a day, and the water at the roots increased. But whenever the temperature is kept up entirely by fire-heat, it should never, as a rule, exceed two or three degrees above seventy, for nothing is gained except weak spindly growth, by an excessive use of fire-heat. As soon as the growth is finished, the plants should be placed in a cooler part of the house, and exposed to as much light as is possible, without their being burnt by the direct rays of the sun. Afterwards from 55° to 60° will be quite sufficient to keep them in health, and much better than a higher temperature; for although I do not agree with the idea of orchidaceous plants growing and flowering without the aid of artificial heat, I am quite certain that it is equally as injurious to coddle them in a temperature of about 75° or 80° through the winter. I have seen plants (and more than once, too) kept in a temperature quite as high as that, but I have never seen them when so treated in such robust health as plants treated in a more rational manner, to say nothing of the time and fuel wasted.

If the drainage is in a good state, and the roots all right, plants growing in baskets and pots will require watering about twice a week through the growing season; and plants on blocks will require dipping every other day at first, then every day, and again every alternate day as they approach a resting condition. During the winter two or three good waterings will be plenty to carry them through. It is much better to let the bulbs shrivel slightly than to keep them too wet. The whole of the species are propagated by division, and some kinds form young plants on the old bulbs. These young plants are best taken off in the spring, and potted firmly in either pots or baskets, or fastened upon blocks, according to which of these methods of culture may be determined upon. I also prefer the spring, just after the young shoots have pushed between one and two inches in length, for dividing the plants, when it is considered desirable to increase the stock by division. I find they take root quicker, and grow away stronger when divided at that stage than they do at any other time. Only very large plants ought to be divided, for one good plant is worth twenty small ones for making a show, and not a quarter the trouble to manage, unless they are intended for sale.

Some kinds are most suitable for growing in pots, others for baskets, and a few for blocks. In the list of kinds at the end of this paper, I will indicate a few which are more suitable than others for growing in baskets and upon blocks for suspending from the roof. The others can be grown in pots, or in the square rustic baskets which are now common in orchid houses, but on account of their upright habit are best stood down on the tables. All baskets and pots must be filled with at least two-thirds of their space of drainage, and the plants should be potted very firm; for as they are mostly tall-growing they are liable to shake about and get loose, as there is not sufficient body in the sphagnum to hold them tight if it is put in loosely. They should be properly tied out as soon after they are potted as is convenient, as the sticks assist to keep the plant in its place. In putting fresh plants on the blocks, the best way is to put a layer of moss, then the roots and base of the bulbs, and cover them with more moss, and securely fasten the whole with copper wire. Very small growing kinds, like *Jenkinsii*, merely require tying on the blocks without the moss.

The best material for growing the dendrobes is good sphagnum, and the next best good fibry peat, with the whole of the fine stuff shaken out from it. The thrip is their greatest enemy, but it can be easily kept down by tobacco smoke. The operation of fumigating must be conducted with care, and not given strong, for the young growth is too tender to stand much of it without injury. Two mild doses are better than one very strong one. If the plants are kept in too dry an atmosphere, the red spider will soon make its appearance, but if a proper degree of humidity is kept in the house, there will be very little fear of their doing any harm.

I shall not attempt to enumerate all the species which are deserving of cultivation, but confine my list to those kinds which are really good, and with which I am personally acquainted:—

D. aggregatum majus.—Rather dwarf growing; blooms in April, with white flowers.

D. alba sanguineum is a very fine kind, the flowers creamy white, with crimson blotch.

D. bigibbum.—This species is a native of New Holland; it grows about a foot in height; flowers in spikes of about six flowers each, the flowers have large round petals of a deep rich lilac colour, with a nearly purple lip.

D. chrysanthemum.—This is a graceful growing plant, suitable for blocks and baskets for suspending from the roof; it flowers in spring and autumn; the colours are rich yellow with dark lip.

D. chrysoctonum, in the way of densiflorum, but has the lip beautifully fringed; the blossoms are produced in spring and are of a rich golden yellow, with a brownish red circle towards the base of the lips. First-rate for specimens.

D. Dalhousianum.—A very strong-growing species, with long spikes of deep rose and purple blossoms, produced at the top of the bulbs.

D. Dayanum is of recent introduction, and first-class.

D. densiflorum is a fine dwarf-growing evergreen, with large handsome spikes of golden yellow flowers.

D. Devonianum is a slender grower suitable for suspending; it flowers in May; the petals and sepals light pink, with a pink and yellow lip. A very pretty species.

D. Falconerii.—This is a very distinct species; the flowers produced on a long spike, with thirty or forty flowers on a spike; the diameter of each flower about three inches; the petals are white tipped with purple, sepals pale rose, with yellow lips.

D. Farnesii blooms in March, with pale straw-coloured flowers.

D. funbratum oculatum is much better than the species (namely *D. funbratum*), as it has the advantage of a brownish red lip. This and *D. Paxtonii* are so much alike that one is sufficient for a moderate collection; it blooms in May.

D. heterocarpum is valuable on account of its doing well in a cold house.

D. Jenkinsii is very dwarf, not growing more than two inches, suitable for blocks only; fine orange-yellow flowers.

D. Kingianum.—The flowers are produced on an erect spike; they are pink spotted with crimson.

D. lituiflorum.—The blossoms of this species are of a pale lilac colour, with deep violet lip.

D. MacCarthie.—This very splendid species is rather scarce and expensive as yet; the sepals and petals are of a rosy purple colour, and the lips white, with numerous small purple spots in the throat, and a purple blotch in the centre.

D. moniliforme, in the way of nobile, but blooms in January; valuable for its early flowering.

D. nobile.—This is one of the very best; flowers rosy purple with dark lip. This can be had in flower from March to June by retarding a few plants.

D. speciosum flowers in January, yellow and white. It is a native of New Holland, and may be grown in a cold house.

D. transparentum.—Native of Nepal; the flowers are rose coloured; a cool temperature will also suit this.

Besides the above, there are as many more first-rate kinds, which should be in collections where there is room to grow them.

GEORGE GORDON.

ON PURE HYBRIDIZATION; OR, CROSSING DISTINCT SPECIES OF PLANTS.

[Read by ISAAC ANDERSON-HENRY, Esq., F.L.S., President of the Botanical Society of Edinburgh, on 14th Nov. 1867, being the opening address of the thirty-second session of the Society, slightly abridged for the *Gardener's Magazine*.]

In the paper I read before the Society in March last, which related mainly to that form of hybridizing generally known as *muting*, and cognate matters—all akin, no doubt, but for the most part *outside* the proper province of hybridization—I intimated my intention of afterwards submitting to you another paper limited to the latter branch in its purer and simpler form. I have now, in laying what I have here to say before you, some things to enumerate which may sound as a thrice-told tale; but as they consist of my own experiences, and as I am animated by a desire to lay them truthfully before you, I trust they will neither over-tax your patience, nor be without some value to those who may be already some way a-field or a-mind to follow in that direction.

1st. I long held it to be of vital importance to have the separate plants intended for the parents in the cross, even though both were hardy, brought under glass, and I still recommend it; for by doing so you heighten the temperature—an important thing—and you can better secure against the interference of winds and insects; and though Darwin holds the former of small account, I have reason for differing with him there. But in the height of summer, pollen may be taken from an outside plant to cross an inside one, and *vice versa*.

2nd. I hold it not enough merely to emasculate the intended seed-bearing flower; I take off every petal, for the petals attract the insects, which seem guided more by their optics than any sense of smell. This act of emasculation in some cases I perform long before the expansion of the bloom, for in many plants—*e. g.*, in the *Papilionaceae*, some of the *Rosaceae*, and *Compositae*—self-fertilization may and does often take place in the unopened flower. This is not all. I sometimes put a *gauze* bag over it; if I do not the mutilated bloom may not escape that most troublesome of all insect pests, the humble bee, which in his unwieldy flight may come across it by pure accident. But for the most part now I make clean work of it, and remove all other expanded flowers on the seed-bearing plant, and allow no kindred one to be near.

3rd. Do not be in a hurry to effect your cross; wait till you find that the stigma is fully developed. In many plants this is shown by a glutinous exudation on the summit, such as in the whole family of the *Ericaceae*, the *Onagraceae*, &c. In other families, such as the *Geraniaceae* and *Malvaceae*, it is indicated by the feathery expansion and recurvature of its separate divisions.

4th. The next thing is to obtain properly-ripened pollen grains from the male plant. This is done by carefully watching when the anthers burst open, otherwise the insects may be before you; and so active are they, especially on such favourite food as the pollen of the *Rubus* tribe, that, to get it at all, I have found it necessary to encase the opening bloom in muslin bags till the pollen was ripe and ready for use. Do not use, as is generally recommended, the camel-hair pencil, which, applied often and indiscriminately, may and often does convey, with the foreign some insidious grains of native pollen, which, however few, are prepotent, and wholly neutralize the former. Take, where that can be obtained and afforded, the entire bloom of the intended

male, and give the slightest brush with all its anthers over the stigma, or all the stigmas if more than one, of the intended female. I will give my reasons for this by and by. You may use for experiment, in some cases, the *long*, and in some the *short*, anthers. To those of the proper dimorphic form I have made some allusion already; they occur in the *Primula* and in some of the *Linum* tribe (as to both of which see Darwin's most remarkable papers in the Proceedings of the Linnean Society). Such anthers, at least two long and two short ones, occur in the two orders of the class *Didymia*, on which I may have a suggestion to offer hereafter, for I think something interesting may be worked out of this form. In cases where the anthers are few—in the *Dianthia*, *Triandria*, &c.—you may use small pinets; a bit of wire so twisted as to form that implement, to carry in the pocket, is by far the handiest; I have used such an instrument all along, and find it better than any other form. In some tribes, the better to secure against invasion by insects, such especially as in some of the *Rosaceae*, having large discs, a muslin bag may be used so as effectually to exclude them; I use it constantly in the *Rubus* tribe immediately after emasculation, taking it off and replacing it after the cross, and keeping it on thereafter till the cross has set.

5th. In some cases it is a matter of some difficulty to procure, and when procured of no less importance to preserve, pollen. In dioecious plants—say the *Aucuba*—a friend may have the male and you have, as we all have, the female in abundance. You would like to store that pollen till your female plant—generally later—comes into flower. Many hold that pollen cannot be preserved in a vital condition for more than one or two, perhaps three weeks. In a recent publication which refers to this matter—namely Max Wichura's "Observations on Hybridization"—of which a very lucid abstract, carefully digested and translated from the original German, by the Rev. M. J. Berkeley, is given in the January number of the *Journal of the Royal Horticultural Society*, that eminent authority holds it as "a fact of great importance that the pollen of willows retains its potency for some time. In some cases pollen ten days old was efficient, while vitality was still further prolonged by steeping it in a solution of honey" (of which I have doubts). "Pollen," he adds, "of *Salix Silesiaca* eight days old seemed almost as potent as ever: in twenty-eight days the traces of vitality were very slight, while that of *Salix cinerea* had become weak in sixteen days." Now I am not aware that there is less vitality in the pollen of willows than in that of any other family; and as many experimentalists hold kindred views to those here enunciated by Wichura, I deem it a matter of some importance to give you one or two instances of my own experience. I have carried in my pocket the pollen of *Rhododendron* again and again from six weeks to two months and upwards, and still found it potent. Of the Japanese forms of the genus *Lilium* I have kept pollen effective in the same manner for equal periods. In fact, generally speaking, I have found the pollen of most plants to remain good for similar periods. Having last year got the new and beautiful *Clematis Jackmanii* to flower, and anxious to preserve its pollen as long as possible, I collected and stored it in its anthers in a simple pill-box. On the 4th of July, 1866, I so gathered and put it into a drawer of a cabinet in my own sitting-room, where it remained wholly away from damp. On the 5th of June, 1867, having first carefully emasculated a flower of *Clematis candida*, I crossed it with the pollen, then eleven months old, and from this cross, I have this autumn gathered and sown eight well-developed seeds. Now, both parents are hybrids, with a large infusion of *alien* blood in them, so that here the vitality was put to its severest test. I notice this result here (somewhat out of place) to suggest the propriety of storing and, if needful, of importing pollen, which, if wrapped up in silk paper, might even, enclosed in a letter, reach this country still potent, by the overland route from India, or, after two or three months' voyage, from all parts of South and North America. Let collectors and friends in distant countries be instructed as to this, and we may soon have an improved progeny of the rarest things, even before such novelties from which they are derived have been obtained from their own seeds in this country.

6th. There is, I humbly hold, another matter of much consequence to be attended to in the crossing of distant species; I mean the times and seasons for effecting the cross; yet not one of those most experienced in the art, from Darwin downward, have touched upon this point. I have had it forced upon my attention for more than twenty years, and found that I could, on some few happy days which occur throughout the season, successfully effect crosses I could not effect with all my care at other times. I have adverted to this in the paper I formerly submitted to you, and again I cannot pass it by. I have some crosses to tell you of which I effected at such times, and might have tried in vain to accomplish them at times less favourable. If you have, say two plants of *Rhododendron*, one a tiny thing, to cross with a large species, or if you wish to attempt a cross between an Indian azalea and a rhododendron, of which I will have to speak hereafter, watch for a propitious time. Such times occur, often few and far between, when there is less of sun than of that latent form of heat, which frequently occurs before thunder, from the air being more than ordinarily charged with electricity. Or it may occur in the spring season, when that form of it which chemists designate by the term *ozone*, is present, whose influence I have often found tell most favourably in promoting the germination of long-sown seeds, of which please pardon my notice of a single instance here. It was to the presence of this, or to some other form of electrical agency, I attributed the almost simultaneous germination of some New Zealand seeds, of a shrub which I got from that country under the name of "Black Maupan," a species of *Pittosporum*, which sprang up together on the morning of the 16th March, 1863, after they had lain dormant two years and eight months. Such atmospheric conditions, to whatever cause they may be due, I have found not infrequently to occur with the east winds of March and April, of which we have so much at that season; at which times I have seen many other long-sown seeds spring quite suddenly and unexpectedly into life. Seize upon all such seasons for difficult crosses. As to the time of the day, you may operate best perhaps from 10 a.m. till 6 p.m.

We shall suppose the cross now performed. Your next anxiety will naturally be to find out whether it has taken. Almost all experimenters have noticed that soon—I would say from six to ten days—an alteration is observed on the stigma and style. On the first you will find its viscous matter dried up and the latter begun to shrivel. You will naturally conclude that it is all right, and that the fertilizing pollen has now passed down into the ovary, and in some cases you may be right; but these appearances are deceptive, especially if you find the style maintain an erect position. The following degrees of failure noted by Wichura have so often occurred in my own experience, that I cannot do better than cite them in his own words, from the Rev. Mr. Berkeley's translation, already alluded to, which I only alter according to my own experience: 1st, The organs submitted to hybridization (the stigma and style) soon wither, but do not in all cases soon fall off. 2nd, The ovaries swell and ripen, but do not contain a trace of

seed. 3rd, The ovaries may seem filled (I say may seem partially filled), having in some instances the small protuberant swelling outside as if seeds were within, and yet no seed be there. 4th, Seeds are present, but small, languid, and incapable of germination. 5th, Seeds apparently perfectly developed, but do not germinate. 6th, Seeds germinate, but the young plants are weak, and wither in a short time, dying off oftentimes after developing the seed-leaves. I have had all these conditions and results amply illustrated; and of the second in the above category, I have had, last summer, mortifying proofs in the muling operation I tried, by fertilizing a flower of the new *Arabis blepharophylla* with my still newer *Draba violacea*. The cross, to all appearance, had taken; the seed-pod swelled better than the others where no experiment was made, and while the valves of the siliques of these last opened and showed no trace of seed in them, the former remained closed, showing by outward development that two seeds were certainly within. But I found on opening, when to all appearance ripe, not one seed was there, though there was a something, which, however, bore no resemblance to a seed—an utter abortion. While Wichura's accuracy in the above degrees of failure are consistent with what I have myself had ample experience of, I cannot, from like experience, endorse the views he has formed on some of his successful results. At page 72 of the above article in the *Journal of the Royal Horticultural Society*, Mr. Berkeley, commenting on Wichura's paper, observes: "Gärtner, indeed, supposes that in genera which are rich in species, there are some which have a prepotent influence when hybridizing, so that in some hybrids the type either of the male or female prevails. Amongst the various hybrid willows, though the genus is so rich in species, and so prone to hybridizing, Wichura has never seen a prepotent type, and doubts Gärtner's statement, especially as he makes it in very qualified terms;" upon which Mr. Berkeley very judiciously remarks on the difficulty of determining, "by examination of types, whether, for example, a hybrid is more like the mother or father—the perfect distinction is subject in many cases to great difficulties, since very much depends on the subjective view of the observation; for, in consequence of the frequent intermingling of both characters, the one observer finds in a hybrid the maternal type, while another thinks the paternal type prevalent." By which I regard Mr. Berkeley as very modestly dissenting from his author. And further on, at page 78 of the same journal, Wichura speaks out still more absolutely. "When both parents," says he, "belong to the same species, we cannot tell what part the male and female parent take respectively in the formation of the progeny. But dissimilar factors are united in hybrids, and an intermediate form is the consequence. The products which arise from reciprocal crossing in plants, unlike those which are formed amongst animals, are perfectly alike." I regret to differ from so great an authority as Wichura, and must venture to demur to the doctrine in more decided terms than Mr. Berkeley does. I have had so many instances of hybrids taking sometimes to one side and sometimes to another—but most frequently to that of the mother—that to those who, like me, have tried their hand with many genera, it would be a matter of supererogation to give instances; I have had them by the score. The converse is the rarer case—i. e., where the paternal type comes out most marked. Yet I remember one eminent instance of a seedling *Veronica* (from the batch of seedlings from which I obtained *V. Andersonii*, *V. salicifolia*, *V. speciosa*) being so like the male parent, *V. speciosa*, that I presented it to a friend in the belief it was purely and simply the latter species; but when it bloomed, it showed, by the longer spike and lighter and brighter colour of the flowers, and by their being a bright crimson instead of very deep purple, which is the colour of the flower of the *V. speciosa*, that the blood of the *V. salicifolia* was there. I can well understand that, as respects the family of willows, from their being so attractive to bees, and from their being naturally so prone to intermix (in so much that few can tell what is a species and what is a hybrid), Wichura has not much overstated the fact, and that a distinct intermediate form may generally be reckoned on. But I must dissent still more strongly from what he lays down in continuation of the above passage at page 78, as to reciprocal crossing. "The products," he says, "which arise from reciprocal crossing in plants, unlike those which are formed among animals, are perfectly alike. It is of no consequence which is the male and which the female parent. It is, therefore a mathematical necessity that the pollen-cells must have just the same part in the act of generation as the ovules." And, based mainly on this doctrine, he follows up and amplifies it in a series of aphorisms which, he admits, are to be "considered conjectural, and require to be submitted to proof," an admission for which he is to be commended, and all the more if he submitted to the like test the dogma on which they mainly rest; for it humbly appears to me that it had been suggested from his experience among the *Salices*—of all plants the most mongrel in a state of nature. Now, in all this it appears to me to be implied by Wichura, that if a distinct intermediate may be formed, and is formed, by crossing A on B, so may an exactly similar intermediate be reciprocated by crossing B on A. And M. Naudin, I observe, in his experiments among the *Daturas*, enunciates the same belief, and holds "that there is not a sensible difference between reciprocal hybrids of two species." That distinguished observer, like Wichura, seems to have confined his experiments to herbaceous or soft-wooded plants. But, from a long and large experience among both hard and soft-wooded plants, I demur, 1st, to the capability of the parents being in all cases made subject to such reciprocity; and, 2nd, to the dogma, where such reciprocity does hold, that the progeny are perfectly alike, whether A or B supply the pollen.

1st, In my various crossings I have had my hands on many hard as well as soft-wooded genera—in particular, I would here instance among the former the tribe rhododendron. There I have again and again been baffled to reciprocate a cross which on one side was comparatively easy to be effected. When the lovely and fragrant *Rhododendron Edgeworthii* first bloomed in this country, all were eager to see its beauty and perfume transfused into dwarf and hardier forms. Some tried the cross by making *Edgeworthii* the female or seed-bearer, others by making it the male. I tried it in both ways, but, for my own part, all those efforts failed where I attempted the cross on the *Edgeworthii*. But while it would not be brought to bear hybrid seed, I had no great difficulty in effecting a cross from its pollen on *R. ciliatum*, another of Dr. Hooker's beautiful Sikkim species having all the desirable requisites of hardiness, dwarf habit, and free-flowering tendency; and, singularly, just as I had obtained and sent off blooms of this brood to lay before the Committee of the Horticultural Society of London, Messrs Veitch, of Chelsea, anticipated me in having a plant of this identical cross first exhibited before that Committee, which is now well known and generally cultivated under the name of "Rhododendron Princess Alice." Now, neither I nor any one who ever tried it, so far as I know, ever effected the inverse cross of *R. ciliatum* on *R. Edgeworthii*; and if they did, the progeny would long ere now have appeared in nursery catalogues. But more of this

below, though there is yet one other instance I may notice now as an illustration of the matter I contend for here. In my former paper I noticed, as an exception to a rule I had found almost general—viz., that European had great aversion to cross with Asiatic species—that I had, notwithstanding, effected such a hybrid by crossing *R. cleagnoides* (another of Dr. Hooker's acquisitions, a tiny Sikkim species) on the European *R. hirsutum*, and of having sent the survivor of the two plants which came of it to Kew, of which, by the way, Dr. Hooker writes me, that it dwindled away and died after being a few years in their hands; but by no possible means could I invert that cross, or get that same very interesting tiny yellow-flowered species, *R. cleagnoides* (a form of *R. lepidotum*), to submit to a cross from any species whatever.

I shall now advert to the second point which Wichura lays down as a dogma—viz., that the progeny of reciprocal crossing, whether it is A on B or B on A, are precisely alike. While my past experience goes with what I observed last summer, it may perhaps suffice to give the latest instance. Having, through the kindness of Dr. Hooker, obtained seeds of beautiful new Californian *Arabis* (*A. blepharophylla*) with large fine rose-tinted flowers, I felt desirous to infuse that colour into some of the other kinds I possessed. After trying it on several, especially on *A. albida*, all in vain, I at last effected a cross,—a reciprocal cross—between it and *A. Soyeri*, a white-flowered kind, something like the *A. albida*, but with a glabrous foliage. Of the cross *A. Soyeri* on *A. blepharophylla* I have raised six plants, the product of two very largely developed seed-pods. These plants are alive and healthy, and promise an improved vigour over either parent. That the cross was sure I had the best proof from there being no seeds in the normal pods of the seed-bearer. Of the inverse cross from one weakly seed-pod I raised one plant, which, after maintaining a sickly existence for some two months or so, has died off. But while this last cross was equally certain as the others, like it, the plant had more of the mother than the father in it. In fact, I have oftentimes found the maternal type most marked in hybrid progeny. I have various crosses effected between distinct species of the rhododendron, where, while the male manifests his presence, the female type prevails. I have it in *R. Jenkinsi* crossed by *R. Edgeworthii*, *R. Caucasicum* by *R. cinnamomeum*, and the hybrid from this latter cross crossed again with *R. Edgeworthii*, and especially the Sikkim species *R. virgatum* crossed with another of my hybrids, *R. ciliatum* by *R. Edgeworthii*—all having more the foliage and the aspect of the mother than the father.

I have another hybrid of the same *R. virgatum*, the female parent crossed, I believe, by *Rhodothamnus chamaecistus*, a tiny procumbent plant of three inches, but all set with flower-buds—not, as in the male parent, at the tips of the shoots, but, as in the female, at the axils of the leaves. I have stated my belief that the *Rhodothamnus* is the male parent, but I cannot do so confidently, from the tallies having got into confusion—the specimens being planted out. But as some plants were obtained from that cross, and as this is the smallest, I regard it as likeliest to be the true progeny; and the cross being an extreme one—a mule, in fact—it is open to question. But as I have this season effected still more extreme—certainly more unlikely—crosses in that family, where there could be no misarrange, you may, I think, take it as true in the meantime. But I could overwhelm you with proof. Darwin, at page 333 of the last edition of his "Origin of Species," has observed the above tendency. "When two species," he says, "are crossed, one has sometimes a prepotent power of impressing its likeness on the hybrid; and so I believe it to be with varieties of plants."

Naturalists of the highest note—Gärtner, Kœrleuter, Naudin, and Wichura—are far from being at one on the subject of variability, as Darwin has shown, especially as relates to crosses, first, between species and species; second, between species and varieties; and, third, between mongrel offspring. But this is a complex subject, and when such high authorities are not at one, and Darwin admits that he cannot reconcile them, it is manifest that the case is still open to further probation. Please excuse me for citing him again in dealing with the views of Gärtner, to whose testimony he deservedly accords great value (page 331). Gärtner, whose strong wish "it was to draw a distinct line between species and varieties, could find very few, and, as it seems to me, quite unimportant differences between the so-called hybrid offspring of species and the so-called mongrel offspring of varieties. And, on the other hand, they agree most closely in many important respects. The most important distinction is, that in the first generation mongrels are more variable than hybrids; but Gärtner admits that hybrids from species which have long been cultivated are often variable in the first generation; and I have myself seen striking instances of this fact. Gärtner further admits that hybrids between very closely-allied species are more variable than those from very distinct species, and this shows that the difference in the degree of variability graduates away. When mongrels and the more fertile hybrids are propagated for several generations, an extreme amount of variability in their offspring is notorious; but some few cases, both of hybrids and mongrels, long retaining uniformity of character could be given. The variability, however, in the successive generations of mongrels is perhaps greater than in hybrids." So reservedly does Darwin deal with a subject on which a flood of the opinions of others could be brought to bear; but as they are not all concurrent, and not unfrequently conflicting, which they may well be from the various subjects experimented on, he has said, with commendable moderation, all that can be said on the subject.

From you, gentlemen, I respectfully claim the same kind indulgence which Darwin has shown to the testimony he has had to deal with, in judging of the views I have offered, and am now to offer, on the experiments I mean, as briefly as I can, to lay before you. But ere I enter upon them it is necessary to premise, especially as regards that form of dimorphism which occurs among many tribes—in all the Jannæan classes from *Pentandria* up to *Decandria*—in having very generally one if not two pairs of anthers shorter than the other anthers in the same flower. And the same dimorphic form often occurs in even a more marked degree in many tribes of the class *Tetrandria*. Besides, as you know, and I have noticed, it is the distinctive character of the two orders of *Didynamia* to have two long and two short stamens.

As observed in my former paper, it is now seventeen years since my attention was drawn to the long and short anthers, but to the latter more particularly in some muling operations there alluded to, where by using them, I crossed that large species of rhododendron, *R. cinnamomeum*, on the pigny *Rhodothamnus chamaecistus*. I refer to these short stamens again as the means by which I succeeded in effecting some extraordinary crosses which, I confidently believe, but for their use and my improving a propitious time, would have been utterly impracticable. As I have said, I at first worked only with short stamens. These I use in all cases where I wish to cross a large on a small species. I have now found that the converse holds, and use the long stamens where I wish to cross a small on a large species. In all extremes I use the longest or shortest pair of stamens as the case demands.

The short pair is generally well distanced by the others—the longest pair often not just so much in advance. There is often an intermediate pair of short stamens, which in cases less extreme are exceedingly serviceable, but there are seldom such intermediates among the long ones. My reason for the use of these short, intermediate, and long stamens is intelligible enough. If I wish to cross a large on a small species, the smallest-grained pollen being in the short stamens, I take the pollen of these stamens of the large plant as best fitted to pass down through the tubes of the stigma to fertilize the ovaules of the smaller species, and so effect the cross on it; and so, *caeteris paribus*, with respect to the other forms.

As this paper has already so far exceeded the limits I intended, I shall not go far back on past years, but restrict the instances I am now to cite to the last few years, noticing,

I. CASES OF CROSSING WITH SHORT STAMENS.

The first cross I shall notice is one I have already alluded to—viz., *Rhododendron virgatum* with my own hybrid rhododendron *B* (*R. ciliatum* crossed on *R. Edgeworthii*); and as this cross is memorable and instructive in several points of view, it is proper to give you its history. On April 20, 1864, I find from my note-book that “I took off all expended blooms of *R. virgatum* and castrated all unopened ones on the plant, there being none left for self-fertilization; done in fine sunshine—west wind—with three short anthers of *B*”—i. e., the hybrid male, being the identical cross which produced Veitch's rhododendron, Princess Alice. Of this cross I ripened four pods of seed, which I sowed on January 28, 1865, and with some failures, got up by December that year seven nice healthy plants, all of which, however, save one, I lost by an accident. That one plant is now setting for bloom—not at the axils, as the female parent (*R. virgatum*) generally shows, but at the extremities of the shoots, as in the male (*R. ciliatum* crossed by *R. Edgeworthii*). But, as I have had occasion to observe already, the type in all else is more that of the female than of the male parent. By the mother's side this plant is a hybrid, by the father's it is a mongrel, and yet it has a fair share of vigour in it. As in its sexual aspect, so in its height, it is that of the mother. Some few cilia are noticeable on its leaves, but it has none of the tomentose or dense hairiness of the male parent; and so in this also it partakes most of the glabrous foliage of the mother. Again, this doubly-crossed plant, and the crosses which produced it—all extreme—show how such crossing may hasten on the reproductive or flowering state. Never in all my experience have I seen or heard of rhododendrons offering bloom at two years of age, for it is only now rising in the third year of its being. I have rhododendrons now fifteen years from seed which have never shown the slightest tendency that way, though ten or twelve years I would consider about the mean at which they attain their flowering state. If by such crosses the like precocity can be generally secured, practical florists may turn them to some account in their profession. You will please observe that I am now dealing with *hard-wooded* shrubs, where there is in general more fixedness of structure and habit than in those on which the physiologists I have cited have chiefly experimented, and which are less liable to be modified by the manifold influences which affect the more pliant and shorter-lived herbaceous genera.

2nd. The next cross in the rhododendron tribe effected by the short stamens to which I would direct attention is very recent, and one with which I took the utmost pains to prevent miscarriage. The beautiful *R. jasminiflorum* of Java, with its delicious perfume and its long tubular five-lobed flowers, of snowy whiteness, so like *Erica Aitonii*, so like, too, in form and fragrance, the sweet-scented jasmine, and so unlike all its own congeners, is the subject of it; and as I regard this cross of some scientific as well as of some practical value, I shall offer no apology for taxing your indulgence in giving you particulars. I made it the subject of many attempted crosses by many of its own tribe, all of which failed except two, which, by the way, afford a good illustration of what I alluded to in my former paper of the *sympathies* of plants, and perhaps, too, of natural selection, though whether it be in the mode which Darwin regards as leading to diversity of species I cannot positively assert, yet I think it is worthy of his consideration. Well, while it rejected so many of its legitimate brethren of the rhododendron tribe pure and simple, I was somewhat surprised that it took kindly with my hybrid *B* already noticed—i. e., *R. ciliatum* crossed by *R. Edgeworthii*—a hybrid of the first degree, having large flowers of three inches diameter, perfumed, and also of snowy whiteness. After the bloom had been long emasculated, on April 17, 1867, I effected the cross with the short anthers of the hybrid *B*. The cross took admirably—the seed-pod swelled, and was pulled fully ripe about 12th July last. On the 15th of that month I sowed the seeds. For the purpose of comparison, I sowed a pot of its own plain native seeds which I had gathered previously, and had, in fact, sown it some ten or twelve days before I sowed the cross. These are both now up. While the native seeds have produced a fair show of feeble plants, the crossed seeds have come up in more than double the number of plants, doubly vigorous in growth and habit, and with leaves so much larger than those of the normal form as to remove all doubt about the verity of the cross.

3rd. The next illustration I have to give you is of a small-leafed Indian *Azalea* eighteen inches high, which I crossed with the tall and robust shaggy-leafed *Rhododendron Edgeworthii*. Two things more unlike in every feature from which to effect a union can hardly be imagined. Yet, with the short anthers—and it was with the very shortest I could find on *R. Edgeworthii* that I effected it—the cross, after careful emasculation, was done on 6th May last. The seed-pod swelled to its due dimensions, and appearing to be ripe, I cut a slice off it, and sowed the seeds so early as the 13th, and the residue on 28th, September last, and I have now got up one or two plants. If I shall be so lucky as to bring it to maturity, the progeny of this cross (one never before accomplished, perhaps) should be a sweet-scented azalea, having a rose variegation like the female parent, a novelty in its tribe; for though the *Azalea sinensis* has been crossed by rhododendrons, I am not aware of any authentic cross, or cross of any kind, between the rhododendrons and this proper Indian azalea.

4th. I have still further a cross of the same nature, between another Indian azalea and the *Rhododendron jasminiflorum*, the latter being again the seed-bearer; and I here refer to it mainly as showing another tendency of this rhododendron towards natural selection, or rather perhaps of *sympathy* between it and remote species, if not genera, for the azaleas have till lately been regarded as a separate tribe from the rhododendrons. The cross was effected in August last, when it again rejected its more natural allies, and formed a union with the Indian azalea, a late rose-coloured spotted variety, a seedling of my own raising. The seed-pod of this cross is now at maturity.

5th. But I have now to call your attention to a cross in the same family bearing on Darwin's doctrine of *natural selection*, or of *sympathy*, in a still

more remarkable manner, which I effected last summer between that most gorgeous of all the rhododendron tribe—namely, the lovely white, large-flowering, sweet-scented *R. Aucklandii* of Dr. Hooker—and an Indian azalea, the latter being the seed-bearer. I made the cross on two separate days on two separate blooms, carefully emasculated some time before; and on the same azalea I tried other crosses with several of the rhododendron tribe—viz., with a fine form of *R. arboreum*, *R. Edgeworthii* pure, and the above hybrid seedling *B* (*R. ciliatum* by *R. Edgeworthii*). But while every one of these failed, the crosses by *R. Aucklandii*, which were effected respectively on 30th April and 1st of May, took most kindly. Both pods swelled; and the seed-pods, though green, appeared to be sufficiently ripe when I pulled them. I counted the seeds in one of these pods, and found them to be about 324, all finely formed, but, I fear, too green to vegetate freely, though some which I sowed appear to be coming up. I cannot vouch for this cross being effected with the *shortest stamens*, for the stamens with which I effected it were kindly sent to me from another source, as I did not myself possess the male plant; but as I invariably select the *shortest* for such crosses, my firm belief is, I had so selected these in this instance, and I had a plentiful supply of all lengths to choose from. In the above cases of crossing a *small* with a *large* species, I hold firmly by the opinion that but for the use of the *short stamens* I could not have succeeded. I have few recorded instances of having effected my experiments with them far into other families. I certainly tried the *pelargonium* in a plant I had of the beautiful white-flowered Madame Vaucher. I fertilized a bloom with its two *shortest* anthers, which, however, were very little shorter than the remaining ones; and, from the three seeds which came of it I raised two fine plants, far more compact and somewhat dwarfer in habit than the parent, having the flowers equally fine, and elegantly thrown up above the plant. But the short stamens of this section of the *Geraniaceae* are very little shorter than the others, and I therefore cannot rely much on the results as establishing the hypothesis I contended for in my former paper—namely, that where all other things are equal, a cross or simple fertilization with the short anthers tends to dwarf the progeny—to my belief in which, however, I still adhere. The instances I have given above in this paper support this other hypothesis, that by their use you may cross a large on a small kindred species, a result which, without them, you might not effect.

II. CROSSING WITH LONG STAMENS.

I have made fewer experiments with the long stamens, but I have one before me now no less remarkable, perhaps, for its far-reaching result than any I have alluded to as done with the short anthers. It is a cross which I effected on the tall *Rhododendron formosum*, fertilized with a scarlet-flowered Indian azalea, on the 11th June last. The seed-pod is finely developed, but I have taken care in this instance to avoid pulling it too early. And I may here notice, once for all, that to obtain the seeds of a cross—especially if it be *extreme*—sufficiently ripe, you must allow a longer time for it than for the ripening of the normal seeds on the same plant.

In all the above crosses I had perhaps less an eye to accomplish a purely scientific experiment than to effect a beneficial result; for, after all, it is the *quid sit utile* which those for whom this paper is mainly intended will have most in view; and, in my estimation, science is best promoted when she is made to minister to some useful end.

The following experiment among the species of *Clematis* illustrates my view of *sympathy* as well as of *antipathy*, and, I would add, of *unnatural selection*: Having many years ago (long before the Messrs. Jackman, who have accomplished such wonderful results) been myself working on the members of this genus, I bethought myself of trying my hand anew upon it, with a view to infuse a richer colour into a new and larger-flowering progeny; and, as I have observed already, I managed successfully to cross with pollens kept for eleven months, the beautiful four-petaled *Clematis Jackmanii* on a thirteen-petaled flower of the fine *C. candida*; but it is of a cross on Messrs. Jackman's smaller, but no less beautiful, *C. rubro-violacea* I am now to speak. Though, like its congener *C. Jackmanii*, it sometimes comes with five or even six petals, it is in its general type a four-petaled flower. With a view to improve it in this feature, I crossed it also with pollen of the larger flowered *Clematis candida*, taken from a bloom having seventeen petals, though this *Clematis*—a French hybrid, I believe, from *C. lanuginosa*—is in its normal state a six or eight petaled flower. Though I crossed two flowers, after careful emasculation, I only gathered three seeds, but these all of unusually large dimensions. After the cross had taken, I left the normal blooms on the crossed plant to their fate; and though visited by insects innumerable, and though the native pollen was abundant, not one native seed, or any saving the three produced by the cross, were ever formed on the plant; and the singular thing was that, with its own native pollen, abortive on itself, I successfully crossed the fine double white-flowered Chinese *C. Fortunei*; and a cross more prolific in the seeds it yielded I have not seen in the tribe before. I know not the parentage from whence this *C. rubro-violacea* was derived, though I believe it to be a mongrel with none of the *Fortunei* blood in it; yet mark how kindly the latter took with it—another instance of remarkable *sympathy*; but, though I have no record of it, I think I failed to get *C. rubro-violacea* to reciprocate this cross.

In all these instances of *sympathy* and *antipathy*, and especially in this section of the natural order *Ranunculaceae*, there is something so inexplicable to me, that I can only concur with what Darwin has observed in his paper on the existence of two forms in the genus *Linum*, where at the close, in summing up the good gained by the inevitable crossing of the dimorphic flowers, and numerous other analogous facts, he says, that these all lead to the conclusion that some “unknown law of nature is here dimly indicated to us.” And this law, when discovered, may disclose more mysteries tending, perhaps, to the wider divergence of species, with constitutions and habits better fitted for the climates and localities in which they may be cast, as well as for subserving the purposes they are intended to fulfil in the economy of nature. In looking at *Ranunculaceae*, with their innumerable male and female organs (and the same thing occurs in the *Myrtaceae*, most of the *Rosaceae*, some of the *Hypericaceae*, and in many other families and tribes), the idea was long ago suggested to me, that each separate row, from the outer to the inner circle of the anthers, might have some separate function, just as I believe that the long and short anthers have their separate functions; and with the view of testing the matter, I had the last summer begun experiments with these *outer* and *inner* anthers; but other aims and objects interfering, I gave up the experiment after I had begun it on these *Clematis*.

But to make success certain, it is my custom, as I have already stated, in crossing either of the above polyandrous flowers, to take the entire bloom of one kind, and lightly to come over, with all its anthers, the stigmas of the flower to be crossed, and leave nature to make her own selection. In refer-

ring to the *Rubus* tribe and its species, I am reminded of an intention I expressed in my former paper of perhaps returning to them afterwards. I again tried my hand upon them last summer. But though I tried various crosses among them, and reciprocated the cross, I had no success in any, except between the *R. biflorus* and the *R. Ideus*, and that only where I made the latter the seed-bearer. And to make sure of either event—success or failure—I had the *R. Ideus* early potted and put under glass, emasculating every bloom I meant to cross; and for more security I stripped off all other flowers—nay, more, I put the emasculated flowers under fine gauze bags, to ward off the invasion of insects. When ripe for crossing I removed the bag, and, on effecting the cross, I replaced it. In this way I succeeded in ripening three berries of the cross *R. Ideus* by *R. biflorus*, of which I sowed the seeds between the 5th and 16th July, though as yet none have vegetated. But *R. biflorus* stubbornly rejected a reciprocal cross. Again I tried both of these on *R. rupestris*, and the latter on them; and though *R. rupestris* showed some sympathy with *R. biflorus*, in a slight tendency to form seeds, these came to nothing. In all these attempts I applied, as I have said, all the anthers of the male flower.

I cannot quit this part of the subject without offering some additional suggestions to those of you who wish to act on any hints I have it in my power to give:—

1st. If your desire be to hasten the flowering condition of plants—to cross violently—*i. e.*, where the allies are not too near akin, and, above all, in the case of mongrels; for nature, ere she gives up, ever makes a violent effort to reproduce.

2nd. If you wish to make your hybrid flower more freely, as well as early, adopt the same advice.

3rd. By following it you will find that you have attained a further advantage. Your plant will remain longer in bloom, because most mongrels, especially those among herbaceous or soft-wooded plants, to which these suggestions apply, are impotent to produce seed, or nearly so, and in such cases the blooms remain long upon the plant. I have another idea, not sufficiently tested, however, in reference to the first point among hard-wooded as well as soft-wooded plants, that all such as ripen their seeds more quickly than others (some among the rhododendron tribe ripen seed in half the time that others take) will reach more quickly their flowering state.

Lastly, as to fruits, on which, however, I have only partially tried my hand, I entertain the belief that we are on the eve of a revolution—that by judicious and persevering crossing we may not only transfer the delicious aroma of one to another, and communicate hardier and more abundant bearing habits to the hybrid progeny, but further, especially in stone fruits, such as peaches, plum, apricots, &c., we may, in addition to these advantages, increase the size of the fruits and diminish the size of the stones; and among vines, get rid of, or greatly diminish the number of, the seeds. And all this I hold to arise from that law of nature by which she not merely strains her efforts to reproduce (to which, however, she assigns a limit), but extends it when these have failed, to make provision for her creatures' wants. These views gather strength from what has been already done; and I may especially allude to what Mr. Standish, of Ascot, has achieved among grapes, of whose extraordinary results an interesting account is given at p. 135 of the *Journal of the Royal Horticultural Society* for July, 1866.

In conclusion, permit me to observe that, while my aim has been, in all the experiments I have brought before you, rather to achieve something useful and practical than to test the theories which Mr. Darwin and others—especially the Continental savans—have been so much engrossed with, I cannot refrain from remarking on the results and the conclusions which some of them have come to on prosecuting a series of crossing operations, tending to show that such crosses do and must eventuate in sterility. M. Naudin seems, like Wichura, as already observed, to have limited his experiments chiefly to herbaceous or soft-wooded plants; and among such, especially among calcularias, I too have often found myself brought to the terminus of bitter and hopeless sterility. I remember one instance where I had reached a perfect monster for size in that tribe, but except in that particular it had no other desirable property. Determined, however, to improve it by crossing, I found on trial I could make nothing of it, and on examination I found its stigma was a hollow tube, and that its anthers were hard masses, and contained not one particle of pollen. Man may run into such mistakes, but he cannot thence conclude that unviolated nature does so. Speaking from a general recollection which does not admit of my specifying instances, I have often found among hybrid seedlings some of a vigour which, in that respect, were in advance of either parent. May not such often occur in nature, and, as a naturally selected parent becomes the progenitor of a hardier and more vigorous race (which having in it, according to Darwin's views, a tendency to diverge), may it not culminate in the long lapse of time into a distinct species, and even annihilate the weaker one which gave it being? So that, in nature's crossing, may not fertility and vigour take the place of sterility and weakness, into which she so generally dwindles when modified by man's device?

THE SURE FOUNDATION.

There are two things which speak as with a voice from heaven, that He that fills that eternal throne must be on the side of virtue, and that which He befriends must finally prosper and prevail. The first is, that the bad are never completely happy and at ease, though possessed of everything that this world can bestow; and that the good are never completely miserable, though deprived of everything that this world can take away. For there is one reflection which will obtrude itself, and which the best would not, and the worst cannot dismiss—that the time is fast approaching to both of them when, if they have gained the favour of God, it matters little what else they have lost. But if they have lost His favour, it matters little what else they have gained. The second argument in support of the ultimate superiority of virtue is this: We are so framed and constituted that the most vicious cannot but pay a secret though unwilling homage to virtue, inasmuch as the worst men cannot bring themselves thoroughly to esteem a bad man, although he may be their dearest friend, nor can they thoroughly despise a good man although he may be their bitterest enemy. From this inward esteem for virtue, which the noblest cherish and which the basest cannot expel, it follows that virtue is the only bond of union on which we can thoroughly depend. Even difference of opinion on minor points cannot shake those combinations which have virtue for their foundation and truth for their end. Such friendships, like those of Luther and Melancthon, should they cease to be friendships of agreement, will continue to be friendships of alliance; approaching each other by angular lines, when they no longer proceed by parallel, and meeting at last in one common centre, the good of the cause in which they are embarked.

FRENCH FRUIT GROWING.

By W. ROBINSON, F.L.S.

As my writings, both in the *Times* and elsewhere, have had the honour of being quoted in the *GARDENER'S MAGAZINE*, and as there has been some little discussion of the matters I have treated of, it is with the greatest pleasure I comply with the Editor's request, and put the matter in as clear a light as I can. By so doing, I may in some degree benefit the horticultural public and save myself from misrepresentation.

Now, before we begin, I wish the reader distinctly to understand that there is nothing very extraordinary about French fruit-growing—nothing miraculously useful in what is called the cordon system—nothing about the matter at all, in fact, which should make us hasten either to abuse what is said of it or adopt any of their ways without due consideration. Slovenly fruit-growing is to be found in France as well as in England; but, taking all in all, they are before us in the culture of outdoor or hardy fruits, and, great as we are as gardeners, we must not be above taking a lesson from them in this matter. We are, on the whole, better horticulturists, especially in what concerns indoor plants, and what we may term the luxuries of gardening; but in the management of a fruit garden, and in the culture of vegetables for market, they do very creditable work indeed, and that which is sometimes surprising for its neatness, and the immense quantity they take off the ground. However, fruit is our theme. For centuries the French have been great fruit-growers, and many of the practices now common, or becoming so, in England were old in France before we even introduced them. Let it be distinctly understood that the district I am now speaking of is that of Northern and North-western France—a climate almost identical with our own, and quite as difficult for the fruit-grower in early spring, as is shown by the pains which the cultivators are obliged to take to protect the blossoms. France is divisible into five climates, so to speak—*i. e.*, the Séguanien, or north-west; Vosgien, or north-east; Girondin, or south-west; Rhodanien, or south-east; and Provençal, or southern. These are each distinct, and present many temperatures and varieties of conditions for fruit-growing, but the district which furnishes the peaches and grapes and pears and apples to the Paris market is that of the first-mentioned climate, as changeable and as disagreeable as our own, but warmer in summer as a rule, though not to the degree that is usually supposed amongst ourselves. It is quite common to hear people talking nonsense about the "fine climate of France," although the cliffs of its coast are as readily seen from Dover as if they were those of one of our large estuaries. The araucaria never attains any respectable dimensions in the neighbourhood of Paris; indeed, I doubt if it will live but for a very short time; and not a few things that we grow here with impunity cannot be ventured out there. But I cannot possibly give you a better illustration of the fact that the Parisian fruit-grower is, to all intents and purposes, as little indebted to the climate as ourselves, than by drawing your attention to this wall and its coping.

Fig. 1.

My firm belief is that, by paying wall-fruits as much attention as they deserve, we may attain as good a result as the French; in fact, I have eaten as good peaches from English and Irish walls as the most fastidious could desire, and as good as ever grew in France. But what I complain of is the comparative scarcity of the fruit, and the little attention that is paid to it generally. Nothing affords a more certain result than the peach. With good treatment the crop hardly ever fails; yet, in the presence of this cheering fact, there are hundreds of people with wall-space, either covered by useless climbers or bare, who never enjoy, or even taste, a peach unless they go to that miserably dear place Central Row, Covent Garden, where even when peaches are at their best in autumn, you may see little rubbishy fruit fit for nothing but pig-feeding, and two shades lower in quality than I have often bought in Paris for one halfpenny, marked at threepence each. To see such utter rubbish arrayed in a basket so as to look priggish, if not wholesome, is, as I take it, a sad and lamentable sight. If you want to get a peach that you can eat you must rise to sixpence, ninepence, or a shilling for it, though perhaps, from the disgracefully crowded and inconvenient state of the market, and from other causes which need not be named, the grower of the peach gets not one-fourth the price charged for them. As I have had to stand up for some phases of French gardening a good deal of late, I prefer quoting the following statement as to the price of peaches in Paris to giving my own experiences. It is written in a contemporary journal, by a person unknown to me: "I visited Paris for the first time in August last, and nothing more surprised me than the abundance and the quality of French fruit, accessible as it was to the poorest labourer. I purchased deliciously ripe peaches for one halfpenny each, fine ones for one penny, and for twopence-halfpenny such as I may fairly term superexcellent." Of course, many would say the climate is the cause of this; but I say we can produce quite as good a result in Kent. All the best peaches for the Paris market—all the ripe ones that come to it, in fact—are grown in the neighbourhood of Paris; and in all cases, with a good cultivator, the wood is carefully laid in to ripen, and the walls are coped as herein illustrated. (See fig. 1). It will be seen that there is, in the first instance, a prominent permanent coping (of tiles that overlap each other), and then there are long iron rods that project from under the permanent coping eighteen inches or two feet in a downward direction. Those rods are placed at six feet apart or so. The use of these is to permit the cultivator to slip temporary copings over the walls in spring, and thus efficiently protect them from the frost. I know one cultivator with 4,000 yards of tarpaulin on little light wooden frames, which he places beneath the permanent coping during the season of flowering. When the crop is out of harm's way, they are taken off and stored away for another season. Then the walls are exposed to the light as freely as could be desired. Some growers use little neat straw-mats made to conveniently roll along and throw off the water. Is not this a sufficient commentary upon the great differences of climate supposed to exist between England and northern France? The finest peaches in France come from within a few miles of Paris, not from the sunny south or the balmy south-west. However, the peach is not such a very important object with me as some other matters, and after merely introducing the reader to the village of Mon-

trouil, I will pass on. That is the place where the supply of peaches for the Paris market chiefly comes from, and an interesting village it is; nearly all the land round it being divided into small oblong spaces by the abundant white walls for the peaches that net over the land in all directions. In some of the gardens the cultivation is rather poor and careless, in others it attains the highest degree of perfection. Here is a sketch of

Fig. 2.

what catches the eye soon after entering the very large garden of M. Lepère one of the most distinguished cultivators. The cut can give no idea of the beauty of the tree, which stands against a tall white wall, and shows as conspicuously when its green leaves are as if the highest art of the advertising agent were used to print it thereon. I do not introduce it here as a model for imitation, far from it! It is simply engraved to show the command the trainers have over the trees. There is a finer example in the same garden to illustrate that, namely, the Napoleon peach; but as that has been before now figured in our garden literature, I prefer giving that which delineates the name of the worthy old man who for half a century has cultivated peaches here, and taught their cultivation with success. Every Sunday morning during the spring and summer time, you may see him with his class, teaching every phase of the culture. In this respect he differs a good deal from some of our own market growers, I think. Generally the trees are treated on the spur system, one which we never apply to the peach, and which to our eyes looks odd, perhaps, in connexion with that fruit; but so well do they take care to "equalize the sap" that the lower shoots are furnished as well as the higher, and the very stumps of the old trees are clothed with a spray of young stubby branches, which hide as well as shade their bark in summer. It is only fair to state that these fantastical trees, if we may so term them, are literally paved with fruit. They are however, merely for ornament, and the growers never think of adopting them for general work, preferring the fan, or what they call the palmette, which is like our horizontally trained tree. Our own fan method of training the peach is, when well done, very good; but how often do we see the trees badly attended to, the wall perhaps without an inch of coping, and the trees almost left to chancé during the season when they require most attention—in spring. Public attention has been called from garden walls in favour of more expensive and uncertain modes for a good many years past; but, depend upon it, our fruit gardens will never be what they ought to be till we learn to manage walls well, and to take advantage of every inch of wall-space that we can obtain. I had a letter from Mr. Watson, the manager of Sir Robert Peel's estate at Geneva, to say that in his neighbourhood they have actually covered a village church with peach and apricot trees, and that during the season the sexton, who is a good hand at fruit, gives lectures to the natives every Sunday morning on that art! Now, although I by no means wish to uproot our cheerful old friend the "ivy green" from his own special domain, I must say that there is a vast waste of wall-space in all parts of this country.

We will next turn to what is called the cordon system, of which probably some of your readers think I am an advocate. It has many forms more or less excellent, but of all the lot I have only felt justified in strongly recommending one, and that is the low horizontal cordon for the production of first class apples, and to enable us to do away with standard trees in gardens. (In orchards or outside the garden nothing can be better, but in the garden we want as little shade as possible). *Le cordon est la forme réduite à sa plus simple expression: une seule tige garnie de brindilles fruitières.* Here is a cordon (fig. 4). It is simply a term used to describe a tree with a single stem, and

Fig. 4.

generally these are only useful in special cases—for the fruiting of seedlings, for obtaining a large variety of fruit in a small space, and so on. Generally, the *cordon oblique* that is here illustrated is considered the most useful for walls. The cut given here illustrates the way of arranging the wires for these cordons; but let us come at once to that kind of cordon which has been proved to yield a capital and distinct result, and which is used to a great

extent in France as an edging to the kitchen and fruit gardens. Here is a figure of it. This is a fair figure of some specimens bearing large crops of Requette du Canada that I have seen in France. The splendid apples recently shown at the Paris Exhibition were in most cases gathered from low horizontal

Fig. 5.

cordon trees, and the method is rapidly gaining ground in France, as being the very best of all for obtaining a supply of first-class fruit. It will yet be universally employed in good British gardens, notwithstanding the prejudice that now exists against it in the minds of some of our best cultivators. I desire to be distinctly understood in this matter, as some people condemn the system advocated without knowing anything about it, or even ever having seen a specimen of it. The prejudice alluded to is quite natural and accountable, and arises no doubt from the number of diminutive and useless toy-trees which have been sold to the fruit-growing public of late years. The great disappointment caused by these has given people a distaste for such things. They are right generally; but the particular form I wish to recommend will not disappoint them if they give it a fair trial. It is simpler and better than any method used in British gardens for the production of choice and handsome apples, fine in size, colour, and every quality. The dwarf bush and pyramid apples, so much grown by some, are grafted on the same kind of stock, but there is greater difficulty in training them to a desirable form; much of their wood, leaves, and fruit is not fully exposed to the sun, and altogether they are inferior to the horizontal cordon, of which we give two illustrations. Fig 5. represents the commencement of a line of horizontal cordons, and is the kind precisely suited for making edgings round plots of ground, &c.; or it may, on the other hand, be planted rather thickly on warm borders. To shortly explain the advantages of this method, I have merely to point out that the fruit are larger, and of a finer colour and flavour, in consequence of what we may term earth-heat.

As the apple flowers late, and is very hardy, it generally escapes the severe ground-frosts of spring, and the apple is the only fruit that we can at present recommend to be grown in this way. In consequence of the extreme dwarfness of the line, we may protect them with greater facility than any other form, and as only choice kinds are recommended to be grown, in this way, it may in many cases be considered worth while to do so. The fruit and leaves are fully exposed to the ripening and beneficial influences of the sun. The plan of training is so simple and definite that anybody may manage it. The form to be attained is precisely defined to the mind of the trainer from the day the wire is laid down. We have merely to allow the single branch to grow in the desired direction, and pinch in the side shoots now and then during the summer to three or four leaves, beginning in May with the strong "water shoots," or *gourmands*, which would rob the tree, and continue to attend to the pinching now and then during the growing season. This will induce the shoots to form fruit-buds at their bases; so that, if well managed, the line of cordons will, in a few years, prove a mass of fruitful spurs. Sometimes the point of one cordon is grafted on to the bend of another, but this is not at all necessary or desirable. A good deal depends on the pinching. It must not be done when the shoots are too young, or they will go on continually throwing out as soft shoots the buds that ought to form fruit-buds. These cordons formed a continuous line on each side of the main walk of the fruit and kitchen garden at Ferrières, the magnificent seat of Baron James Rothschild, about twenty-five miles from Paris. The truss of short and well-set buds that ran along in a regular line was ten inches or a foot in diameter, and the whole literally roped with the noblest and best apples in cultivation. A more pleasing sight could hardly be seen in a garden, and it is even prettier when, in spring, the long line is full of flower. Acting as an edging to the fruit and flower borders, it is in the way of nothing, shades nothing, but is, on the other hand, an ornament to the garden. The wire is best supported at from 10 in. to 15 in. from the ground, and great care should be taken to equalize the sap, *i. e.*, pinch the tree so that when full-grown it may be equally furnished with buds in all its parts. A galvanized wire is the best to use.

Fig. 6.

The figure No. 6. illustrates a form equally adapted to the same ends—the bilateral cordon. It is also particularly well suited for laying along at the bottoms of badly furnished walls, and from little trees in such a position we may get such specimens of Caville Blanche apples, such as they sell in Covent Garden for a couple of shillings apiece.

Plant the trees at from six to ten feet apart according to the quality of the soil. Where possible, use the "French Paradise" stock in competition with what is called the "English Paradise," and in fine sandy soils it would be wise to try the Doucin stock, using in all cases good varieties of apples, and taking care to secure a regularly furnished and well developed line of spurs. Space prevents me going into the subject more fully, and there are besides other important things to be spoken of.

Having said so much for this particular cordon, I now pass on to the naturally developed forms, so to speak. Most emphatically do I agree with recent recommendations of yours with respect to allowing trees something like a free development. What a sad and truthful tale that afflicted but eloquent amateur told the other day in your columns. Therefore I beg of your readers, if they have the least supposition of my being an advocate for what are called toy-trees, to banish it from their minds at once; I am nothing of the kind, nor are the French horticulturists. I believe that at this moment there are more poor little diseased and starved and pinched-to-death trees around London alone than in all France! The French are too

well acquainted with the nature of trees to pinch them to nothingness. They allow a free and natural development even to those trees that receive most pinching attention from them. Root-prune they do when a tree requires it; but none of that ceaseless root-pruning is practised by them that has for such a length of time been so prevalent amongst ourselves. Their pyramids generally attain a goodly size and beautiful proportion. They grow cordons of pears sometimes in little gardens, where the proprietor is what we may call a fancier of curiosities in fruit-growing, and for the fruiting of seedlings, &c.; but in general the forms on their walls are large, simple, and natural, and the same applies to the very neat and cheap trellises that they employ, instead of our cumbersome and awkward espaliers. Toy-trees, forsooth! Reader, if I had had but one lesson in this matter, it would have sufficed to teach me that more of what is unsound and bad and costly in practice has been taught and accepted in this matter of fruit-tree cultivation for the past generation than in any other rural pursuit whatever.

Fig. 7.

Not long ago I paid a visit to Oak Lodge, Addison Road, Kensington, one of the most beautifully laid out places near London; it is, in fact, one of Mr. Marnock's very best examples of the villa garden. On passing near the extensive rockwork and charming piece of water, I was struck by the picturesque beauty of a large pear-tree; the leaves and fruit were quite gone. The handsome form of the tree, and the drooping of its long bud-laden side-branches, drew my attention to it, and on inquiring further I found it was a *Beurré Diel*, and one as famous for its supplies to the fruit-room as for its appearance in this exquisite pleasure ground. No pruning, at any time or of any kind, was given to this fine tree; no more attention paid it, in fact, than one of the common deciduous trees of the plantations, yet it is very doubtful if any over-pinched dwarf tree in existence would afford as good a result as even one branch of this noble old specimen, which would be worth growing

Fig. 8.

in such a position for its flowers in spring alone. And so Mr. Marnock must have thought, or he would not have suffered it to remain among the choice specimens of rhododendrons, and other shrubs that embellish the place. For a gene-

ration this tree has borne large crops of fruit, and of twelve dishes of *Buerré Diel* recently submitted to the Fruit Committee of the Royal Horticultural Society, a dish gathered from this very tree was pronounced the best! And the aspect of the fine collection gathered from it on the 15th of this month fully proved that their good opinion was well won. Here is a testimony in favour of full and free development of which few will doubt the value—here a significant commentary upon the unnatural and bad system that we have, in too many cases, followed for years. Nobody will deny but that much good has been done by judicious root-pruning, and that pinching and summer pruning properly carried out are things which we *must* practise and study more and more; but it is their indiscriminate adoption for every case that we have to battle against. That great harm has been done in this direction most practical men know, but the state of our fruit-rooms after Christmas, in ninety-nine out of a hundred of our gardens, abundantly proves it also. The pyramid well managed is a most excellent method for growing the pear, but the pyramid badly managed, and in the state described by the amateur above referred to, and who wrote so eloquently, because truly, is as bad as bad can be. We do not plant half so many pyramids as we ought; but even if we had pyramids as abundantly and as well managed as the French have them, even around little houses, that would be only one step in the desired direction. Here I introduce the reader to a specimen of a class of forms of pear-tree that is largely adopted in the Imperial gardens, and apparently with a very good result. The tree is not large, but so shaped that the branches get an equal supply of nutriment, unlike those of the old espalier. The various ringings in the branches indicate the successive cuttings required to get the tree to its full development. By growing this type of tree on the cheap and neat trellising they adopt in France, the advantages of having a great variety of fruit from a comparatively small space are gained, and at the same time you have what we may term a naturally formed tree. Having alluded to their trellising being adopted in preference to our own old and clumsy way of training espalier trees, it is now time to say all this kind of thing is beginning to be done on a very neat, cheap, and effective plan, in the best French fruit gardens. So many failures have we seen in British gardens as regards the placing on the walls of the wire to which to affix the trees, that it has been given up as a bad job, and many have said that the old-fashioned shred and nail were the best things. But there is a very much better and sounder way, and I am completely converted as to the value of the French mode of wiring a wall, of which fig. 7 is an illustration. It is done with the same galvanized wire they apply to the cordons, and in much the same manner. In the first instance, several strong iron spikes are driven into the wall at the ends—in the right angle formed by two walls, in fact—and then rough nails, or rather hooks, are driven into the wall in straight lines by a mason, exactly in the lines of direction through which we want the wire to pass. The wires are placed at about ten inches apart on the walls, and the little hooks for their support, also galvanized, are placed at about ten feet apart along each wire. The wires are made as straight as a needle and as tight as a drum, by being strained by a little tightener. A man may do as much training along one of these walls in a day as he could in twelve with the old nail and shred. Now, if we consider the expense of the shreds and nails, the procuring and cutting of the former, the destroying of the surface of the walls by the nails, and the leaving of numerous holes for vermin to take refuge in, the great annual labour of nailing, the miserable work it is for men in our cold winters and springs,—it will be freely admitted that a change is wanted badly. The system of wiring a wall above described is simple, cheap, almost everlasting, and excellent in every particular; and it must ere many years elapse be nearly universally adopted in our fruit gardens.

Fig. 9.

To make their capital trellises erect posts of T iron are used, and the same little *raidisseurs*, or tighteners, as are employed for walls and cordons, and, indeed, all their garden wire-work. Fig. 8 will explain this at a glance: it illustrates one of the cheapest and best forms of *raidisseur*. It will be readily seen that no straining-post is required with this kind of thing; the wire being fastened in the axle, and by turning that (which a child can do) we get the degree of tightness required. There are several forms of this all alike in principle. By their use a very slender cheap kind of wire may be used instead of the bolt-like iron we use at present. Here space compels me to finish, though there are several points upon which I had intended to enlarge at greater length.

I have not alluded to the extraordinary way in which I have been attacked for noticing the few merits of French fruit-growing in the *Times* and other journals, and by those who before I wrote had been engaged in praising French gardening for a generation past; but that, perhaps, is better left untouched by me. And, after all, those who endeavoured to throw discredit upon my statements have indirectly done good; for they have led to my being able to call public attention to the matter much more forcibly, and to my ascertaining that our wants in the fruit way are much greater than I had supposed at first. I am not without hope that it may eventually lead to our being enabled to supply our own markets, which we are so far from doing at present, that one importer alone brings to them £10,000 worth of French pears every year, and has done so during years when the demand was less than it is at present.

P.S. Since writing the above I have read an article in the *GARDENER'S MAGAZINE* for the 9th of November, in which the sort of objections that my papers have met with is embodied in a plausible and scientific form. Before I ever said a word about French fruit-growing I knew the exact differences of the two climates, and, what is more, I experienced them. Concisely, I reply to that article by saying, If the climate of France was so hot that the French would have to devise means to keep their trees cool, and I had recom-

mond English gardeners to go and do likewise, its arguments would apply to my case. Otherwise they do not. In the districts of France that I am alluding to, the peach and winter pear are put against walls to get heat, and against walls with a good aspect. I assert that against walls we can grow the peach as well as the French, and as cheaply; and, in other respects, render ourselves independent of them for fruit. Time shall tell us if I am right. Of course at present everybody says I am wrong. *Nous verrons.*

EXPERIMENTAL CULTURE OF GERANIUMS.

In reference to the note which you inserted of mine, at page 464 of your Magazine, and which you have noticed in your article on "Bedding Geraniums," at page 487, I did not intend, by stating the experiment referred to, to ignore the blending of colours in crosses. What induced me to state that experiment without any comment was, that there was hardly a possibility of any mistake in making it, as only the two plants were in flower in the house at the time the seed was obtained, and, having carefully crossed them myself had more faith in that cross than any I ever made, and wished to have the experience of others on the same subject. It is facts, not theories, I wish to advocate. I am well aware we must often use the words "chance," "sport," and "accident;" but it is merely an acknowledgement of our ignorance of the principle or law by which the Governor of all things sees meet to regulate that to which we apply them, for assuredly no such terms can be applied to any of the operations of His workmanship. I am also aware that blending of colours does take place, and, as you observe, were it not so, "there would be but little interest in the proceeding." Still, may blending of pollen (on this subject we have yet much to learn) not arise from insects in some way immediately before or after impregnation by a particular flower, and in this way thwart the operations of the hybridizer. The above experiment is the only one I can point to to prove that such a thing was next to an impossibility, and in *no* case was there a blending of colours of the two parents.

In Lawrence's "Physiological Lectures," I found a case in point from the animal world, which he quotes from Col. Humphrey, and where he states, "the increase of a common ewe impregnated by an ancon (the name given this particular breed) ram follows entirely the one or the other of the parents, without blending any of the distinguishing and essential peculiarities of both. Frequent instances have happened where common ewes have had twins by ancon rams, when one exhibited the complete marks and features of the ewe, the other of the ram." What happens in the animal world may also happen in the vegetable world, and it looks like a confirmation of my experiment.

In the article above referred to, you state "from seedlings derived from Christine in any way, whether as a father or a mother, you would expect about nine-tenths of pink flowers, so powerful is this variety as a parent to transmit its colour to its progeny." In my experiment I did not find it so, for the colours were pretty equally represented by both parents.

This season I have a seedling between Madame Vaucher and Dr. Lindley, the flowers of which I think little, if anything, inferior to the latter in shape and size, but the colour is a light pinkish salmon on a white ground—very pretty; so that it appears to be influenced to some extent in colour by both (supposed) parents (for there were many geraniums in flower at the time the seed was impregnated); although I have seen Madame Vaucher when much exposed to the sun of a very similar colour to my seedling.

I may mention that my experiments on the variegated tribe of geraniums were more to find out the capabilities of these plants to perpetuate their peculiarities than through any love I had for them, although individually some of them are very beautiful. Hitherto I have looked to form in the flower as the first quality in a geranium (I adopt your nomenclature, and discard *pelargonium* from this section), and have taken always a deep interest in your papers on that subject, and feel satisfied they must have done good service in bringing about a sound and wholesome state of things; for however much plants like *Stella*, *Cybister*, and *Black Dwarf* (and they are the best of that class) may yet be necessary to fill up the border, I have no doubt a time is coming when we shall see plants equally capable of withstanding the weather, and making even as good a show there, and yet individually as well formed, as the best shaped flowers we at present possess, such as *Dr. Lindley*.

In bedding geraniums, however, I differ a little from you, and think they should all have plain leaves and be without a zone, so that we may have breadth of colour. The dark zone, in my opinion, swallows up, if I may be allowed the expression, the colour of the flower, and I think is one cause why such plants as *Punch* have so long kept possession of the field.

I am glad to find from *Dr. Denny's* reply to my query that his experience so far agrees with mine, viz., that when the cotyledons are entirely green the plants afterwards exhibit no sign of variegation. This I think is very important when fully proved, and I do not yet find even one exception from it in my own experience; and as this would enable any one with a limited supply of room, and who was only wishing to cultivate variegates, to get quit at once of a great many seedlings, and thereby give the remaining plants more room, and a better opportunity to display their variegation, and also save both time and labour on that which in the end would prove worthless.

I do not know if I understand exactly what *Dr. Denny* means by "The fact of the eye at the foot-stalk of the splashed cotyledons of an entirely green plant assuming the variegation when it pushes into a shoot," &c., &c. We are agreed that if the cotyledon be splashed, that the after foliage of the plant will be variegated, so that if the word "*splashed*" be omitted I can at once see what is meant, as *Dr. Denny* afterwards puts the query, "Are the shoots thus obtained 'to be considered in seedlings as sports?'" In this case I should suppose if a seedling sent out a shoot differing from the original plant, it was as much a *sport* from that seedling as any sport arising from an entirely green plant; the word "*sport*" being given only to cover our ignorance or our inability to give a reason for its production, and we are therefore just as much at a loss in the one case as in the other to account for the change that has taken place. Although the sport from the sporting seedling may not be such a radical sport from the original as the variegate from the green plant, still it is so only in a less degree.

I quite agree with the doctor that much may be gained by comparing notes, and at some future period, as I observe changes taking place, it will afford me much pleasure to communicate them. W.

"Did any of you ever see an elephant's skin?" asked the master of an infant school in a fast neighbourhood. "I have!" shouted a six-year-old at the foot of the class. "Where?" inquired the old man, amused by his earnestness. "On an elephant," was the reply.

Calendar.

WORK FOR WEEK COMMENCING DECEMBER 28.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Make plantations of rhubarb, sea-kale, asparagus, and horse-radish. Roots of dandelion, packed together in leaf-mould and put into gentle heat, will furnish a delicate salad in five or six weeks. Paskall's sea-kale pots are best for the purpose. Keep dung and all soluble matters under cover. Turn over manures, and put aside, in heaps to be frozen, rotted leaves, and other materials suitable for potting, and when well sweetened and pulverized remove to bins in the potting shed to keep dry for use. Get sticks and stakes tied up in bundles ready for use; wheel turf and weeds to the muck-pit; get pots washed and sorted over, and crocks sifted into sizes for the potting-bench. This is a good time to make new drains, improve watercourses, and plant edges. Sow early peas and beans on warm dry slopes; broccoli to be heeled over with their heads to the north.

ASPARAGUS.—See that the soil of the forcing-beds is sufficiently moist. A heat of 55° to 60° will be sufficient, but it must not decline below 55°. Straw hurdles are of great service to prevent a cooling of the bed during severe frost and north-east winds.

RHUBARB AND SEAKALE PUT INTO FORCE.—We object to the usual plan of blanching rhubarb as spoiling it; unless it is acid it is worthless, and the blanching system as followed for the markets only produces a mass of vegetable pulp without beauty or flavour.

PEAS AND BEANS.—Sow in boxes or on a bed in a frame, in case the open-ground sowings are all eaten up, when these will be useful to transplant. The best plan is to sow the seeds on turf-sods, laid grass-side downwards; the turf should be cut about four inches wide, and the seeds sown along the centre, and the whole regularly laid out to form a bed in a cool frame. The process of transplanting consists in removing the sods with the plants into the prepared trenches. As the plants are apt to push through the turf, it is best to lay the sods on a hard surface, so that when lifted there will be no damage to the roots.

GROUND WORK.—Take advantage of open weather to push on planting and ridge up vacant ground to the frost. During frost is a good time to empty muck-pits and wheel out manures; and if the ground is not too hard frozen, turn over the plots that are already ridged to expose a new surface to the frost. When earth-work of all kinds is at a stand-still through severe weather, some good jobs may be found in repairing fences, clearing up litter in the rubbish yard, collecting rough material for paths and drains, and burning weeds and refuse.

Flower Garden.

FLOWER GARDEN.—Bulbs ought to be all planted by this time; but if any remain out of the ground, get them in without delay. Take up tea roses that are in exposed situations, and lay them in by the heels in a shed out of reach of frost. Cut down fuchsias that are to remain out all the winter, and cover their roots with litter or coal-ashes. Pansies, pinks, and other choice things in open beds should have a little light litter sprinkled over them in frosty weather, or be protected with canvas or hoops. Tulips protect in the same way. Look over plants in frames, and take off dead leaves, and keep the plants moderately dry.

BULBS not yet planted must be got in, and as they are unusually fine this season, purchases may yet be made. We always advise early purchasing and early planting; but if we would ever excuse delay it is now, the stock being in such prime condition that the bloom is sure to be satisfactory, though the after-growth may be weak through their remaining out of the ground too long.

CARNATIONS AND PICOTEES.—The young stocks look amazingly well this season. They require plenty of air and very moderate watering, and to be kept clean.

ROSES should now be heavily mulched with half-rotten dung. If the dung is quite green and rank, it will do as well, but thoroughly rotten dung is almost useless as a mulch for roses—in fact, a waste of valuable material. Roses may be planted now during dry weather; the ground to be in good heart, deeply trenched, and well manured. On loamy land broken up from grass roses do better than in ordinary garden soil, and those who grow for show should either use turf liberally or break up meadow ground for their best plants. Get in briars quickly before the best are gone. Manettis layered during summer may now be divided and planted out in rows for budding next season.

EVERGREEN SHRUBS planted now must be heavily mulched with dung to keep frost from their roots.

AURICULAS.—Remove the old decayed leaves, but in doing so be careful not to injure the plants. The plants must never be dust-dry, let the weather be ever so severe. We mention this because during hard weather good collections are occasionally ruined, the growers forgetting how hardy the plant is, and how much its constitution is injured by drought. But beware of damp, and during frost avoid watering until a favourable change occurs, if possible.

CULTIVATION OF THE RANUNCULUS.—To bring the ranunculus to perfection requires generous cultivation; in a poor soil or a dry climate it languishes, and soon becomes degenerate; and at certain seasons it requires vigilant watchfulness, or all previous expense and labour may be lost. But it deserves all the attention that may be necessary; and as there need be no mystery about its cultivation, so every lover of high-class flowers may adopt it as a familiar friend. If you turn to some of the older writers, or question some of the older growers of this flower, you will learn that nothing is more difficult to grow than a fine ranunculus; failure is seen to be more frequent than success; and the whole of this is to be attributed to the quackery and epiricism of men incapable of reasoning on the commonest garden operations. The ranunculus is a tuber which throws out a bunch of fibres, that strike downwards into the soil; it is perennial, loves moderate moisture, and a firm loamy bottom; and as it blooms in the hottest and driest months of the year, it needs frequent watering and occasional top-dressing to prevent excessive evaporation. The proper soil is a rich mellow loam, the proper manure well-rotted cow or horse dung; recent manure ruins it; so do any exciting compounds of night-soil, blood, or chemical stimulants, or excessive quantities of manure of any kind, all of which have been recommended in bewildering numbers, and the proportions stated with ridiculous precision. If the soil of the garden is at all suitable, manure it well in pre-

ference to preparing composts; if it is not of a loamy and somewhat crumbly character, procure the top-spit of an old pasture—one in which buttercups abound is best—ridge this up, turn it occasionally for six months or more, and with this and well-rotted dung prepare your bed. A model ranunculus bed would be formed of loamy soil that had been ridged up and turned over once a month for a year. The old soil would then be taken out to a depth of fifteen inches, a layer of rotten cow-manure two inches thick would then be placed in it, the old-sweetened soil would then be worked up well with half its quantity of decayed stable and cow manure, and with this it would be filled up, and then edged either with some neat and low-growing edging-plant, or with edging tiles, which would have the effect of an elegant stone moulding, with the advantage of being easily removed in altering or breaking up the bed. Arrangements would then be made, by means of hazel hoops and rods, or a properly constructed piece of light iron-work, for the reception of a tarpaulin or canvas, to exclude late frosts, heavy rains, or excessive sunbinc, during the blooming of the plants. Without precisely such arrangements, an amateur desirous of a gay bed of ranunculuses, but not aiming at the production of show flowers, might make sure of a good display by properly planting them in a well-manured loam in a *firm state*, and if prepared three months before planting, all the better. The roots of the ranunculus always work deep, hence a shallow soil is quite unsuitable. A depth of three feet is none too much, and if the lower spit is a sound loam the roots will reach it, and frequent watering will be less necessary. In a very heavy soil a little sand may be added with advantage, but a very slight admixture will be enough. It is getting customary now, as we remarked in this place a short time since, to plant the ranunculus in February; November used to be the month, and, in situations not subject to severe spring frosts, November and December may still be considered the best times for planting. Not that the flowers are finer,—they are simply earlier; and for this gain there is occasionally a risk of losses through frost. The bed ought to be prepared a full month at least before planting, to give it time to settle and become firm, for failure is certain if the soil lies light and spongy. For February planting, the bed ought to be ready early in January, and the best time for planting is between the 1st and 20th of February, the precise day or week being determined by the weather. There has been a good deal of discussion as to the proper planting season, but it is now pretty generally agreed that autumn planting is attended with risk, for which early blooming is the only compensation, and that the first twenty days of February are the safest for collections of any value. In cold, wet, and very tenacious soils, or in exposed situations, it would even be better to defer planting to the first week in March; and planting may be the more safely deferred with the ranunculus than with most other tubers, for they retain their vitality out of the ground two or three years, and, if kept cool and dry, suffer but little exhaustion by delay. To plant a bed of ranunculuses is rather a delicate affair. It should be left to no subordinate who is not thoroughly capable of delicate gardening manipulations. It is a bit of fancy work for the amateur himself, and one in which he will take pride and pleasure. First of all, judge if the soil is in a proper condition. It ought to crumble when handled, and scarcely soil the fingers. If pasty and adherent, the planting had better be delayed till a fine day has dried it a little, for unless the soil can be banded freely, the planting will turn out a clumsy affair. There is more than one way of planting ranunculuses. Some growers mark off the bed, and then just stick the claws of the tubers into the soil, and cover the whole with sand; others dibble them in, in the way that beans are sown by farmers; but the best plan is to drill them. Choose a fine day; have your tubers sorted as you mean to plant them, and you zinc or wooden talleis ready. You have already at the fireside planned how the colours and sorts are to be arranged, and have entered in your note-book all the necessary heads, so that when you begin planting you will have to work only and not to consider. First rake the soil so as to give the bed a gentle convexity; then put down the line for the first row; and with a small pointed hoe, or the corner of a common one, draw the drill exactly two inches deep. The orthodox depth is an inch and a half, but I prefer, and therefore recommend, a trifle deeper, on the principle of giving the root free work before the foliage appears, as well as to escape as much as possible the effects of the very late frosts to which we have been subject for some years past. Into the drill sprinkle a very little fine sand, then proceed according to your book, and plant the first row of tubers, inserting the proper label *at once*, not trusting to memory a single jot. Each tuber must be gently pressed into the soil to about half the length of the claws, care being taken that none of the claws are broken in the process. The drills may be five inches apart, and the roots four inches apart in the drills, though some growers prefer six or even eight inches distance every way. The first mode will not be injuriously close, and it forms a very rich bed. When the drills are filled and talleied, sprinkle a little sand over the tubers, and then neatly rake down the soil over them, and dress up the bed as you intend it to remain. It may be as well to state as a last word on this point, that if the roots are planted too deep they will not flower, for instead of throwing up the flowers they will exhaust their energies in forming new tubers near the surface. Be careful, therefore, never to make the drill more than two inches deep. As soon as the plants begin to push through, the bed should be carefully trodden over between the rows, firmness of the soil being the prime element of success in the general cultivation. If the weather is dry, they may be watered night and morning, and if the soil has not been so liberally manured as it ought, weak manure water may be used. The ranunculus likes a moist and generous soil, but nevertheless it is a mistaken notion to water it either frequently or copiously. Artificial watering never does as much good as is expected of it, and if it can be dispensed with it will be better for the plants. It is a good plan to mulch the bed with moss or old tan, or even ancient and well-sweetened manure, placing the dressing neatly along the rows. Such a procedure will frequently obviate the necessity for watering, and carry the plants through till the rain falls. This is a flower which rarely disappoints us, if it is properly treated. It needs a quiet sort of culture. Excessive drought, moisture, manure, and stimulating nostrums of all kinds, are inimical to success. The tubers should never be placed in immediate contact with manure; they should never be planted deeper than two inches; and should be arranged with the nicest care. Then for two whole summer months you will have a glowing carpet of colour, in which the brightest dyes will blend and mingle to form the softest, most harmonious, and boldest contrasts. The following list comprises the best sixty varieties of show ranunculuses known: Costar's Apollo, Crimson Apollo, Auriga, Ann Hathaway, Alexis, Balcon, Beritola, Com. Napier, Coronation, Cedo Nulli, Campardown, Chevlier, Delectus, Delight, Dr. Darwin, Dr. Horner, Edgar, Eliza, Eva, Exhibitor, Eupatoria, Fairy, Postus, Grand Prior, Gover, Goldfinder, Herald, Henning, Horatio, Humboldt, Indicator, Jenny Meldrum, Kilgour's Princess, Liffey, Lord Gough, La Téméraire,

Lord Berners, Marquis of Hereford, Miss Forbes, Melanthon, Meekness, Miriam, Mustapha, Mackenzie, Mary Howitt, Miss Gair, Model of Perfection, Mélange, Melpomene, Miranda, Mrs. Travers, Naxara, Oceana, Orange Brabançon, Oeil Noir, Orissa, Playfair, Petrel, Preceptor, Pertinax.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Dig round old fruit-trees, and lay down a layer of old dung six inches thick, in a ring, three feet round the stem of each, and the size of the fruit will be improved next season. Trees that are sufficiently luxuriant should not have manure. Root-prune any trees that grow too luxuriantly to bear well. Give protection to any tender fruit-trees, and lay boards in a slope over vine borders to shelter them from excessively cold rains. Unmail from the walls the younger shoots of tender wall-trees to prevent premature breaking. Let nothing lie in by the heels an hour longer than can be helped. Bush fruits properly taken up and properly planted ought not to miss the move in the slightest degree, but you are sure to lose a whole season if they lie about waiting to be planted. Strawberry beds may be made this month, but it is not a good time to plant strawberries.

Bush fruits should be planted, potted, pruned, and manured. Burn the prunings, and if the ashes are not wanted for any particular purpose throw them round the roots of trees; they are powerfully fertilizing. Gooseberries and currants may be lightly forked between to mix the manure with the soil, but raspberries should have three or four inches of dung, not very rotten, laid over the piece, and the soil between them should not be dug at all. Orchard-house trees may be pruned at once, and washed with a solution of eight ounces of Gishurst's Compound to a gallon of soft water.

APPLE AND PEAR TREES infested with moss or vermin may be much benefited by being painted all over with a mixture of Gishurst's Compound and clay, or a mixture of lime, soot, and clay. If the painting is entrusted to a boy, take care that he applies the brush by an upward movement; if allowed to brush downwards, many spurs will probably be destroyed.

Greenhouse and Conservatory.

GREENHOUSE.—Chrysanthemums will keep the houses gay till after Christmas, when the first lot of forced shrubs, especially azaleas, will come in to take their place. In the conservatory, whatever flowers are at command may be made the most of by judiciously intermixing with them good plants of Yucca, Acacia lophantha, Camellias, and others possessing characteristic foliage. Hard-wooded plants in the greenhouse must have as much air as the weather will allow, and as little water as possible, as we may soon expect severe frosts. The thermometer should not descend below 38°. Soft-wooded plants will be subject to mildew if the house is at all damp, and must have fire-heat during foggy as well as during frosty weather. Shift any specimen plants that are in need of increased root-room. Peaches to fruit early must be frequently syringed, and have as little fire-heat as possible, but the heat may be allowed to rise, with plenty of ventilation, during sunshine. Ericas must have air at every opportunity, and, if forced with other flowering shrubs, must have the coolest place in the forcing pit, and be very gently stimulated. Greenhouse temperature, 40° to 45°.

CONSERVATORY.—Let nothing suffer now for want of fire-heat. Forced bulbs will require warm positions, but Heaths, Epacris, and other hard-wooded plants may be at the cool end. For succession now, Mignonette, Primulas, Violets, Lily of the Valley, *Luculia gratissima*, Poinsettias, Euphorbias, and *Justicias* are particularly valuable. Keep the atmosphere pretty dry, to prolong the bloom of Camellias, Azaleas, &c. Average temperature 45° by night, and 55° to 65° by day.

PELARGONIUMS to be kept as much as possible without fire, but to dry the house it may be useful occasionally. The fancies need warmth the most. Specimens may be tied out, and late-struck plants be shifted on. Give water with caution.

BEDDING PLANTS should be looked over occasionally, and the pits and frames emptied and filled again to clear away all dead leaves and ensure a good airing. Amateurs have many losses through lack of attention to this work, and mildew makes havoc unseemly while there appears to be nothing the matter. Short of actual frost, the more air the better, and if water is wanted give a good soaking on a fine morning when the barometer is high and steady, so that the balls may get a little dry again before change of weather to wet or frost.

VERMIN.—Now that gardeners have a little breathing time is a good opportunity of cleaning frames, lights, and the under sides of stages, and other places where vermin harbour. In the stove there is often great need of such work when there is no time to do it.

CAMELIAS.—These to have similar treatment to that advised for Azaleas. The whole stock ought to have been disbudded long since; if neglected, do it now, for generally speaking the plants are loaded with more buds than they can expand properly. Plants coming into bloom to be assisted by sprinkling the borders, paths, and pipes occasionally, to allow a diffusion of vapour. There is no class of plants that more enjoy atmospheric moisture, but as the blooms expand they require a drier and cooler air.

CINERARIAS throwing up their flower stems to be put in an intermediate house for early flowers. The most backward to be repotted at once, so as to make fine specimens for a very late bloom. Keep the stock clean, use sulphur where mildew occurs, and fumigate for green-fly. Give particular care now to specimens for exhibition; remove small shoots, and peg down those that are best placed to produce a round and solid head of bloom.

Stove and Orchid House.

STOVE.—We suppose the cultivator to be able now to furnish the conservatory with showy specimens of *Euphorbia Jacquiniflora*, *Poinsettia pulcherrima*, *Gesnera zebrina*, *Begonias*, *Lucentias*, *Camellias*, &c., &c., from the stove. But there must be a succession, and one of the first things to consider now is how to make the stove available, not only for the preservation of its ordinary inmates, but to forward furnishing plants for other structures. *Phim-bago eupensis*, *Cytisuses*, *Azaleas*, and *Camellias* should therefore be introduced at the coolest end of the stove, if there is room for them; a few *Roses* may be forced with them, and many ornamental-foliaged subjects will be found useful if in a clean and healthy state. Mixed stove selections must now be kept rather cool, as growth is not desirable. Keep the atmosphere of the house sweet by giving air on fine days, and be careful to remove dead leaves, mosses, and liverworts in pots, and whatever impedes the circulation of air or engenders unwholesome vapours. All plants approaching a state of repose to have little or no water. Plants in active growth must be watered with caution; let them have enough, but see that they do not stand in pans with stagnant water about their roots, or in wet places in the midst of mildew. Temperature of stove, 60° by night, 60° by day, with a rise of 10° during sunshine.

ORCHID-HOUSE.—In collections where there are now only a few orchids

in a growing state, the forcing-pit may be turned to account to receive them, so as to allow of the cooling down of the orchid-house, and securing thereby a complete state of repose for the plants, which is scarcely possible if there happen to be a few fine specimens pushing into bloom, or in an active state of growth. It is at this time of year we see the full value of divisions which can be respectively devoted to orchids from different climates and requiring now different temperatures. Orchids at rest to be kept comparatively cool and dry; 50° by night and 60° by day will be sufficient. Variegated orchids must have very little water now, and if in a warm house will do better without than with bell-glasses; they are, indeed, generally kept too close. Rot and spot are diseases peculiar to this season, and are the result of too much moisture in the house or of drip from the glass.

Orchids that may be in bloom in December.—*Angraecum bilobum*, *eburneum*, *eburneum superbum*, *sosquipedale*; *Arpophyllum spicatum*; *Barkeria elegans* and *Skinneri*; *Bletia Shepherdii*; *Brassavola Digbyana*; *Burlingtonia amoena*; *Calanthe vestita rubra oculata*; *Cattleya maxima*; *Warscewiczii*; *Calogyne Gardneriana*, *media*; *Cymbidium giganteum*, *Mastersii*; *Cypripedium insigne*, *insigne Maulei*, *purpuratum*; *Dendrobium album*, *moniliforme*; *Dendrochilum glumaceum*; *Epidendrum vitellinum*; *Grammatophyllum speciosum*; *Laelia acuminata*, *albida*, *anceps*, *Maryanii*, *peduncularis*; *Leptotes bicolor*; *Lycaste Deppeii*, *Skinneri*, *Skinneri alba*; *Miltonia Karwinski*; *Odontoglossum maculatum*, *membranaceum*; *Oncidium Barkerii*, *bicallosum*, *Cavendishii*, *incurvum*, *unguiculatum*; *Phajus grandifolius*; *Schomburgkia crispata*; *Sophranites cernua*, *grandiflora*, *violacea*; *Zygopetalum brachypetalum*, *Mackayii*.

Forcing Pit.

FORCING.—Keep asparagus going for succession. Rhubarb, seakale, and French beans will soon be in request. Lay a few picked tubers of early potatoes on a warm flue to sprout for planting over dung-heat; and get a bed or two ready.

FORCED PEAS AND BEANS.—Tom Thumb is the best of all peas for forcing; sown now and grown in pots, in the same house with French beans, it will give a good return. Those who force for Covent Garden sow in October and November. This pea is of dwarf branching habit, and of very little use for outdoor work, being tender in constitution.

VINES breaking to have a gradual rise of temperature, beginning at an average of 55°, with a rise of 10° during sunshine. As the vines acquire a vigorous growth, raise the heat so as to average 65° by day and 60° by night when they come into bloom. Too sudden a rise will make long joints and weakly growth, independent of the injury to the crop. A warm dry border will do as much as the best management of the temperature of the house.

CUCUMBERS.—Bearing plants will require occasional watering with liquid manure, and as much light as possible to keep them in health. Remove male blossoms as fast as they appear. Keep the atmosphere moist; temperature, 60° by night, 70° to 75° by day, 80° with sunshine. Sow singly in pots for succession plants; we can particularly recommend for present sowing Carter's Champion, Cuthill's Black Spine, Highland Mary, and Telegraph.

MELONS for a first crop to be sown at once. Sow them singly; it is no gain in the end to have to divide them when several seeds are sown in one pot; it is too great a check.

Correspondence.

PLANT-HOUSES, CONSTRUCTION OF.—Having a corner, of which I enclose a plan, with the dimensions and purpose I should wish to carry out marked thereon, I shall feel greatly obliged by your informing me whether it would be better for my object to make the front of glass or brick. The roof is intended to be a span, the back rafter, about 8 feet long and about 13 feet high at the apex, of rough plate-glass. Would not this be the best, proper shading being difficult to accomplish? The ferneries are intended to contain rockwork. I should like also to know what quantity of 3 or 4 inch hot-water piping would be required for each, and the best place for laying it, particularly in the stove, as the other parts would require but little heat.

B.

[So far as we can understand your case from the plan and description given, it appears that you propose to have one span-roof the whole length, to be divided into three compartments; and you ask what quantity of piping would be required for stove-ferns and the other two cool houses, and where it would be best to place them all. These questions we cannot answer definitely, as you do not show where you will have the entrance to either house, nor give us the position of the boiler, if you already have one, or if not, where you intend to place it; nor do you give any description how you will arrange the interior of the two ferneries. If we knew where you intended to enter each house, and the position of your boiler, we should have no difficulty in giving you the advice you require; but in the absence of this need-

A HOUSE 25 FEET HIGH. Back wall, 37ft. long, 13ft. high,

Front at present open, faces due south-west.

In information we can only suggest what appears to us, at this distance, as the most desirable position. Assuming that you will enter each house separately from the front or south-west aspect, at A A A on the plan, we have shown the number of pipes required in each case, and, as will be seen, the position of each is the same. Considering the width of the houses, and the purposes for which they are required, it would add to the room considerably if the pipes occupied a chamber just under the floor of the house, with an iron grating over them to let out the heat; the space over the chamber with an additional width will serve for the walk; 4-inch pipes would be the best. As to rough plate-glass doing away with the necessity of shading, my experience of it in a very large conservatory would lead me to choose the ordinary glass, and to fix inside the roof a shading of tiffany of a rather stout texture. If this is fixed to the roof on the first outburst of summer weather, and taken down again on the approach of autumn, it would answer every purpose, and with care last a long while, and its appearance in houses filled with such subjects as you propose gives to those who are inspecting them a sort of security against heat, and actually makes the houses look cooler than they really are in the heat of summer. A brick wall, 3 feet above the ground level, and the remaining part glass, would be the best for the front, allowing for the doorways. Having answered your questions in the best way we can from the details given, you will allow us to ask you how you think you will like the interior of the houses, if built as you suggest, after they are finished. Our idea is that you will be disappointed with them, and therefore offer the following suggestions for your consideration. Would it not be best to divide the whole into two spans, running north and south, or nearly so, with a division in one span to form the cool houses, the other to be used as a stove fernery? or, if you like it better, let the largest be the cool fernery, and one of the divided ends for the stove. We like the appearance of the span as you propose from the outside, but we feel sure we should dislike the appearance of the hip from the inside, unless the houses had a stage in the centre, and could be entered at B, so as to come in under the centre of the span.]

STEWART AND SMITH'S FLANGE STOVE.—Having seen several inquiries about stoves for heating plant-houses in the GARDENER'S MAGAZINE, I send you a very rough sketch of one that we have had here for two or three years. It is the best stove that I have ever seen in more than thirty years' practice. We have it in a conservatory of the Gothic style; it is about 34 ft. by 13 ft., with three roofs, a high centre one, and one lower on each side.

Owing to the centre of the house opening into the middle of the front hall, we were obliged to place the stove at the west end; if it could have been placed in the centre, half the firing would have heated it; as it is, it consumes about one bushel of coke in twenty-four hours—such weather as we have had lately—to keep the house at 50° by day and 40° by night. The stove consists of about twenty pieces bolted together. Ours was put together by a carpenter, and all the bolts were finished with red lead. It is about 20 in. in breadth each way, and 24 in. high.

J. H.

GARDEN SEEDS.—Unless there is a great alteration in the sending out of seeds, gardeners will never know what they have sent them. For instance, a gardener sees some kind of vegetable strongly recommended by yourself or some correspondent, and writes for it with his other seeds, and the parties send some seed with the name on it that he sent for; but nine times out of ten he finds it anything but what he sent for. Now, why don't seedsmen either say they have not got it, or don't know where to get it, and not send some spurious article in its place? I was served thus by the highly spoken of Northumberland white celery in 1866; and a gentleman near here got some celery this year that was to be the finest grown, and grew the whole of his crop from it, and has not a stick fit for the table. How provoking, after all the labour, to find it good for nothing at all! Then, again, as regards Snow's broccoli, as your excellent correspondent, Mr. Clarke, says, how difficult to get it true! I had some called Snow's in 1866 with the celery above-named, and instead of its being a nice dwarf kind like Snow's, it grew from 2ft. to 3ft. high, and never headed at all, but was cut down with the frost like a cauliflower. Then, again, the cauliflower, how difficult to obtain it true to its kind! Also that old, but one of the very best lettuces, the brown Bath black-seeded Cos; if you write for it you most likely (at least I have always found it so) get a black seed, and when you have grown it, there is not one in ten, and perhaps none, of the true kind; but as soon as it is full grown, and you think of tying it up for hearing, it is running away, so you have none for the table after three months' work, sowing, planting, &c.

Toddington.

JOSEPH HUNT

Why is a woman mending her stockings deformed? Because her hands are where her feet belong.

MEASLES AND CUCUMBERS.—A lady who had two children sick with measles wrote to a friend for the best remedy. The friend had just received a note from another lady, inquiring the way to pickle cucumbers. In the confusion, the lady who inquired about the pickles received the remedy for the measles, and the anxious mother of the sick children with horror read the following: "Scald them three or four times in very hot vinegar and sprinkle them with salt, and in a very few days they will be cured."

Replies to Queries.

Carnations, Picotees, and Pinks.—Constant Reader.—It is our rule not to recommend dealers, and you must therefore discover for yourself, where to buy what you want. The following collection comprises the cream of the several classes: **CARNATIONS:** *Scarlet Flakes:* Christopher Sly (May), fine; Sir H. Havelock (Puxley), Rising Sun (Kirtland), Mrs. Holland (Hardman)†, Illuminator (Puxley), John Bayley (Dodwell)†*.—*Purple Flakes:* Earl of Stamford (Elliott), Squire Mynell (Brabbin), Mayor of Nottingham (Taylor)†*, Premier (Millwood)†, Florence Nightingale (Sealy), No. 10 (Kirtland), No. 3 (Kirtland).—*Rose Flakes:* Lovely Ann (Eley), Lord Belper (Eley), Poor Sam (May), Rose of Castile (Heady)†*, Alice (Kirtland), Mr. Martin (Elkington).—*Scarlet Bizarres:* Admiral Curzon (Easom), Dreadnought (Daniels), William Pitt (Puxley), Captain Thompson (Puxley)†, Sir J. Paxton (Eley)†*, Challenger (Puxley).—*Crimson Bizarres:* Tenby Rival (Puxley)†, Hope (Puxley), Monarch (Puxley), Misnomer (Puxley), Phidias (Puxley), No. 50 (Kirtland)†*.—*Pink and Purple Bizarres:* Falconbridge (May)†*, Shakspeare (May), Captivation (Taylor)†, John O'Groat's (May), Sarah Payne (Ward), William Catleugh (Puxley).—**PICOTEES**—*Heavy-edged Red:* Ne Plus Ultra (Heady)*, Mrs. Norman (Norman), Favorita (Kirtland), Countess of Wilton (Kirtland), Mr. Lachner (Turner), Exhibition (Elkington).—*Light-edged Red:* Engenie (Turner), Mrs. Reynolds Hole (Turner), Miss Holbeck (Kirtland)*, Ada Mary (Smith), Duke of Wellington (Turner), Lanretta (Smith).—*Heavy-edged Purple:* Lord Nelson (Norman), Rival Purple (Heady)*, John Linton (Heady), Duke of Buckingham (Elkington), Mr. May (Turner), Countess (Fellows).—*Light-edged Purple:* National (Kirtland), Amy Robsart (Dodwell), Princess of Wales, ex. ex. (Kirtland); Eliza (Payne), Rev. G. Jeans (Kirtland)*, Neah Robiusion (Kirtland).—*Light-edged Rose:* Rosy Circle (Payne), Bertha (Warris), Lucy (Taylor), Mrs. Taylor (Taylor)*, Mrs. Sewell (Kirtland), Rev. H. Matthews (Kirtland).—*Heavy-edged Rose:* Flower of the Day (Norman)*, Elise (Kirtland), Princess Alice (Kirtland), Miss Meeking (Kirtland), Leua (Kirtland).—Those marked with asterisks are the best six in each class; those with daggers the best twelve.

Gloxinias.—New Beginner may keep his gloxinias wherever they will be dry, and in a temperature averaging 40° to 50°. They may be started from January to March in a moist heat of 70°, whether in a propagating house or on a dung-bed is no matter. Hotbed culture is the favourite method with many of the old-school of cultivators of this flower.

Camellia Propagation.—New Beginner.—The safest modes are by inarching and grafting. About the end of March is the best time for inarching; the stocks employed are seedlings of single flowering varieties; they are slightly started into growth before being inarched upon, and after the operation is performed growth is promoted by a steady moist heat. Grafting may be done now as well as any time in the year, and onwards to the end of February. This method makes shorter legged plants than by inarching, as the stocks can be cut low down. If the grafts are put on in autumn or winter, it is best to keep the grafted plants in a cool-pit, giving very little or no air at all until growth commences, and then a little heat will assist them greatly. But if the grafting is deferred till late in spring, it is advisable to place them in a gentle heat immediately afterwards, that the junction may be promoted by a free circulation of the sap. Camellias may be struck upon their own roots. The proper time to make the cuttings is when the new wood is half ripe, say about the middle of June. The cutting pots should be filled with a mixture of peat and sand equal parts, with an inch of pure sand on the top. The cuttings ought to average four inches long, and be put in close together, and be covered with bell-glasses. A spent hotbed or cold frame is better than any hotter place for them. Propagation by cuttings of single varieties is practised for raising stocks for grafting the double varieties on, though seedling stocks are to be preferred. But the double-flowering varieties are rarely multiplied in this way, for on their own roots they do not usually thrive so well as when grafted.

E. S.—Your variety of *Scolopendrium* is singularly bold and handsome. Secure the plant by all means, and as soon as possible divide it, and when you have half a dozen plants, and the forking and tasseling continue constant, will be time enough for determining upon a name for it. It sometimes happens that a year's cultivation of a sport like this resolves it back to the normal form, and, of course, there is an end of all interest in the matter.

June.—The *Gardener's Magazine* is registered for transmission abroad, but there is no stamped edition published. The weight of two numbers, with wrapper packed for posting, is under four ounces, and two may thus be forwarded to any part of the United Kingdom for one penny.

A. C.—We have frequently considered the matter you refer to, and hope shortly to accomplish the end desired. "Country Life" is published at 10, Bolt Court, Fleet Street, London, E.C.

J. H., Tuddington.—We have no recollection of the notes you refer to. If you can make amusement of it, send what you wish to say on the subjects you name.

Plants for a Miniature Aquarium.—J. L. W.—*Hydrocharis morsus ranae*, *Riccia fluitans*, *Lemna* of several kinds, common *Nitella* and *Callitriche aquatilis*. You may extend the list by referring to Hibberd's "Book of the Aquarium." The last two will require to be fixed at the bottom amongst pebbles, the others will float.

OphioGLOSSUM lusitanicum.—It will be seen by advertisement in this week's issue that Mr. G. Wolsey, of Guernsey, will supply six plants of the "adder's tongue fern" for 12 penny stamps. Some time last year Mr. Wolsey made a similar offer, and many of our readers benefited by it. Mr. Wolsey states that this curious fern may be grown with others under glass. It should be watered all through its dormant season at the same time as the others. It becomes much handsomer under good cultivation than when growing wild.

Slugs and Worms.—C. F. G., Birmingham, has a small garden in an elevated spot, which is "absolutely full" of slugs and worms, and he wishes to know how to get rid of them. Assiduous attention to a few definite modes of destruction will accomplish all that C. F. G. desires. At this time of year there is not much to be done, but in mild weather slugs will be found in plenty, feeding on any scraps of decayed vegetation. As spring returns they will become very active, and then a regular system of killing should be adopted. Now there is no system so safe and certain as sprinkling fresh lime in powder wherever either snails or slugs abound. In the course of a few days the lime loses its virtue, and then becomes a fertilizer, so that to give a sprinkle once a week all through the spring will be to kill the slugs wholesale, and benefit the soil at the same time. If we had such a case to deal with, we should sow great quantities of lettuce-seeds in spring, and keep

the beds regularly sprinkled with lime; the lettuces will attract the slugs from all parts, and the lime will kill them. Nothing could be more simple. When the summer is advancing, little heaps of refuse vegetables will make good traps for slugs. Let the heaps lie for a week undisturbed, and the slugs will collect in them from all quarters; then turn them over and sprinkle with fresh lime, and again they will be destroyed wholesale. As for the worms, frequent tilling will do them sufficient mischief.

BIBBERGIA splendens.—No Name.—This is essentially a stove plant, requiring a temperature of 65° to 80° in summer, and 55° to 65° in winter. The proper soil is one consisting of equal parts loam, leaf-mould, chippy cow-dung, and sand. When growing freely, liberal allowances of water are necessary, but at other times the supplies should be rather sparing.

Removable Greenhouse.—I should be much obliged if any of your readers could give me some information on the following matter. I am desirous of erecting a small greenhouse sufficient to keep alive during the winter cuttings of geraniums, verbenas, and such ordinary bedding plants. As, however, I am holding a curacy which I may vacate at any moment, I am anxious to have my greenhouse removable. How can I best accomplish this? All the so-called removable greenhouses I have seen require a certain amount of brickwork. Does not this render you liable to have your house claimed as a fixture?

W. J. F.
[The only form of house obtainable in a ready manner which admits of removal is that known as Sir Joseph Paxton's patent. This is placed on brick or concrete piers, but there is no question of its legal removability, the house resting on but not being fixed to the piers. Any skilful constructor of plant-houses can, however, design a house which shall be as firm as a rock and yet admit of removal without difficulty.]

India-Rubber Tree.—A correspondent writes thus: Why is an India-rubber plant like a terrier? Because the smaller the more valuable. Ex.: My friend having a plant which he bought young at 2s. 6d., and kept till it is 5 ft. high, wished to exchange it for shorter plants. Seeing one in a seedman's window he asked the price, and was told 7s. 6d. He naturally supposed his fine, straight, well-grown, and vigorous specimen to be worth at least four small ones, but was informed that it was worth nothing!

[This is nothing new or surprising. When an India-rubber tree has been cut down, the after growth is never so elegant as the clean, straight, single stem of a plant that has never known the knife; and for a window tree a moderate-sized specimen is to be preferred to an unwieldy giant. In ordinary cases the only good purpose to which a large specimen can be applied is to furnish cuttings for propagating. In exemplification of the fitness of *Ficus elastica* for parlour culture, we could name a clergyman who has grown several in his drawing room, and when they became too large has presented them to the Crystal Palace.]

CATALOGUES.

SMITH AND SIMONS, GLASGOW. *Catalogue of Gladioli, 1867-68.*—A beautifully printed alphabetical list of all the best named varieties in the market. Lists of liliams and kitchen garden seeds for early sowing are added.—*Catalogue of Roscs.* A full descriptive list, with letters attached to the names to indicate which are best for exhibition, for town gardens, &c., &c.

JAMES BACKHOUSE AND SONS, YORK.—*Hardy Trees and Shrubs, including Conifers.* This catalogue is arranged on a new plan, separate sections being devoted to ornamental trees, to shrubs thriving in common ground and shrubs thriving in peat earth: in each section the genera and species are arranged alphabetically. There are separate lists of rhododendrons and climbing shrubs. It is admirable in every respect except its shape, which is a heterogeneous square, like "Notes and Queries; a form unsuited for binding with other catalogues.

Othello was lately performed at Hayti by a company of negro actors, and the part of *Othello* was taken by a black man who painted his face white.

"What brought you to prison, my coloured friend?" "Two constables' sah." "Yes, but I mean, had intemperance anything to do with it?" "Yes, sah, dey was bofe of 'em drunk."

Diogenes being asked why it was that philosophers sought the society of the rich much more than the latter sought theirs, replied, "Because philosophers know what they want, but the rich do not."

A little girl of three years was saying her prayers, not long since, when her little brother, about four years old, came slyly behind and pulled her hair. Without moving her head she paused and said: "Please, Lord, excuse me a minute while I kick Herby."

Sir Philip Francis (the author of *Junius*, according to Lord Macaulay) says "The most dangerous of men is an active fool. There is not stuff enough in a fool to make an honest man. It is possible to cure a fool of a folly, but you cannot cure him of being a fool."

A witness spoke of a particular person as having seen him "partially clad." "Was he not quite nude?" asked the examining counsel. "No, sir," replied the witness; "he always wore a pair of spectacles."

BUFFALOES STOPPING A TRAIN.—Recently on the Pacific Railway, in Kansas, between Ellsworth and Hayes, an exciting encounter took place between a herd of buffaloes and a passenger train. For three miles the buffaloes pushed along parallel with the train. Many shots were fired, but nothing stopped the tide of the stampeded beasts. Finally they swept across the track, ahead of the locomotive, fairly worsting the iron horse by bringing him to a halt.

STRENGTH OF CONCRETE WALLS.—Determined to see for myself what had been accomplished with concrete, I visited the concrete houses at Gravesend; and, fortunately for my conviction, I arrived at the time of the examination by the committee of the Metropolitan Board. I saw a 9-inch concrete wall battered with a 14lb. sledge hammer. Mr. Vulliamy, the architect of the Board, said that with about three such blows a hole would have been made through a 14-inch brick wall. I cannot say what number of blows were inflicted, but certainly the wall was struck vigorously, the only perceptible effect being a slight crushing of the stones on the surface of the concrete on the side hammered. Mr. Vulliamy tested the wall on the other side with a straight-edge, and declared that not the slightest effect was produced.—*Builder.*
